Is wax a necessary constituent of the diet of wax moth larvae? M. H. HAYDAK (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 581-588).—An experiment conducted at the Minnesota Experiment Station indicates that wax is not an essential constituent of the food of the wax moth larvae, since they were successfully reared to the adult stage for two generations on a number of media which did not contain even traces of wax. "A deficiency in the development of the wax moth was observed on a food consisting of powdered dried yeast mixed with sawdust. The best development of wax moth larvae was achieved on foods having liberal supply of all the essential food constituents as applied to rats. A formula of an adequate food for rearing of wax moth larvae is given."

Winter mortality of larvae of the European pine shoot moth (*Rhyacionia buoliana* Schiff.) in Connecticut, A. S. WEST, JR. (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 3, pp. 438-448, figs. 3).—Observations of the effect of winter temperatures on the survival of the European pine-shoot moth during the severe winter of 1933-34 as contrasted with the preceding two winters, together with the results of some laboratory experiments on lethal low temperatures, are reported.

Sugar-cane varieties in Antigua in relation to (a) infestation, (b) field losses by the moth borer (*Diatraea saccharalis* Fabr.), L. L. DE VERTEUIL (*Trop. Agr. [Trinidad]*, 13 (1936), No. 5, pp. 130-135, figs. 2).—A description is given of various types of injury to sugarcane by the sugarcane borer, and previous investigational work in connection with the differences in varietal susceptibility to borer is referred to. Two variety tests were conducted with reference to infestation and percentage loss in weight by the moth borer, the results showing that the percentage loss in weight is not necessarily proportionate to the percentage joint infestation and that there is a significant difference between varieties when compared on measurable field losses (percentage loss in weight).

The incidence of the large moth borer *Castnia licus* in wild plants in Trinidad, D. VESSEY-FITZGERALD (*Trop. Agr. [Trinidad]*, 13 (1936), No. 2, p. 37).—Observations made during an unsuccessful search for a parasite of *C. licus* in Trinidad at the end of 1933 and early in 1934 have shown this moth to be attached to plants belonging to unstable communities under conditions of

only moderate shade, although extending into more stable plant associations in the absence of shade.

The effectiveness of cultivation as a control for the corn earworm, G. W. BARBER and F. F. DICKE (*U. S. Dept. Agr., Tech. Bul. 561 (1937), pp. 16, figs. 2*).—Experiments with simulated and actual plowing of three types of soil at Charlottesville, Va., and one type of soil at Savannah, Ga., during the period 1928-33, for the purpose of determining their effect on the control of the corn earworm, are reported.

"Piedmont red clay, sandy loam, and an artificially made high-humus-content soil were used at Charlottesville, and a fine sand soil was used at Savannah. Cages containing these soils were fall plowed and spaded, spring plowed and spaded, and fall disked, respectively; control cages in which the soil was uncultivated accompanied each series of treated soils.

"It was found that each kind of treatment was an important factor in reducing the number of moths of the corn earworm emerging from hibernation. Fall plowing reduced moth emergence most, fall disking least, and the effectiveness of spring plowing lay between these two treatments. Each operation is a material aid in the control of the insect and can be employed where its practice meets cultural and economic conditions to best advantage. The high-humus-content soil (a mixture of cow manure, sandy loam, and red clay) appeared to be very favorable to the development of the parasitic fungus *Sorosporella uvella*, which killed the pupae, so that during a 5-yr. period in which experiments were carried on no moths emerged from hibernation from this soil."

Digestive enzymes in the southern armyworm, F. H. BARBERS and P. A. WOKE (*Jour. Agr. Res. [U. S.], 54 (1937), No. 7, pp. 547-550*).—With a view to determining the enzymes normally present in the digestive tract, a series of qualitative tests were made, using the southern armyworm reared on foliage of turnip and cabbage plants. The tests were made on extracts of the contents and tissues of the foregut, midgut, and hindgut, on regurgitated material, and on extracts of the labial glands. "The approximate H-ion concentration of the contents of each part of the digestive tract was determined colorimetrically. The contents of the foregut had a pH between 7.6 and 8.0, those of the midgut had a pH of 8.2 in the fore part and 7.7 in the rear portion, and those of the hindgut and the excreta a pH between 7.4 and 7.6. Amylase, maltase, glycogenase, invertase, rennin, lipase, trypsin, and erepsin were found. The location of these enzymes in the various sections of the gut is given. The presence of raffinase is doubtful, and tests for the presence of lactase, cellulase, emulsin, and pepsin were negative."

Control of larvae of diamondback moth (*Plutella maculipennis* Curtis), H. G. WALKER and L. D. ANDERSON (*Jour. Econ. Ent., 30 (1937), No. 3, pp. 443-448, fig. 1*).—Experiments conducted by the Virginia Truck Experiment Station (E. S. R., 73, p. 508) led to the dusting of kale plants infested with newly hatched larvae of the diamondback moth on October 31 and November 10 at the rate of about 25 lb. per acre "with derris-talc and cube-talc dusts containing 0.5 percent rotenone, both in combination with and without Aresket. The derris-talc, derris-Aresket-talc, and cube-talc dusts gave 82 percent control and the cube-Aresket-talc dust gave 87 percent control, indicating that there is very little difference between the effect of any of the dusts, and that, if applied when the larvae of the diamondback moth are young, either a derris-talc or a cube-talc dust containing approximately 0.5 percent rotenone and 2 percent total extractives will give satisfactory control of this insect."

The life cycle of laboratory-bred *Anopheles albimanus* Wiedemann, L. E. ROZEBOOM (*Ann. Ent. Soc. Amer., 29 (1936), No. 3, pp. 480-489, fig. 1*).—

A study of the life cycle of *A. albimanus*, an important carrier of malaria in Panama, is reported upon.

Variations of seasonal cycle in the genus *Tabanus*, H. H. SCHWARDT (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 589-592).—The observations here reported, which supplement earlier studies at the Arkansas Experiment Station (E. S. R., 76, p. 221), have shown "that *T. lineola* and *T. atratus* can develop from egg to adult during one summer, though the latter usually requires a year. *T. sulcifrons*, *T. costalis*, *T. lasiophthalmus*, *T. benedictus*, and *T. trimaculatus* all require approximately a year for development. *T. stygius* usually requires approximately 2 yr. for development, but certain individuals emerge after spending only 1 yr. in the immature stages. Rarely an individual of *T. atratus* will hibernates two winters before producing the adult."

Pangoniinae of Utah (Tabanidae: Diptera), J. A. ROWE and G. F. KNOWLTON (*Ohio Jour. Sci.*, 36 (1936), No. 5, pp. 253-259, figs. 14).—This contribution from the Utah Experiment Station lists 15 species of pangoniid horseflies as occurring in that State, of which one is described as new under the name *Chrysops dilatatus*.

The biology of *Leschenaultia exul* Townsend, a tachinid parasite of *Malacosoma americana* Fabricius and *Malacosoma disstria* Hubner, H. A. BESS (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 593-613, figs. 24).—Biological investigations of *L. exul*, a common leaf-ovipositing tachinid parasite of the eastern tent caterpillar and the forest tent caterpillar in the northeastern part of the United States, conducted at the Gypsy Moth Laboratory, Melrose Highlands, Mass., during the years 1933, 1934, and 1935, are reported. Having but a single generation a year in New England, it overwinters in the soil as pupae within the puparia. "The adult flies emerge in the latter part of April and the first part of May, and deposit their eggs on the foliage of trees fed upon by their hosts. Eggs may remain viable for a period of 26 days after deposition. The reproductive capacity of a single female fly may be as high as 5,000 eggs. The eggs are ingested by a host larva feeding on the egg-infested foliage. Hatching of the eggs occurs within the alimentary tract, and the tiny maggots migrate within a short time to the salivary glands of the host. The first-instar maggots complete their development within the salivary glands and molt into second-instar maggots just prior to or after migration from the salivary glands. In the second instar an integumental funnel is developed and the maggot remains within this funnel until the larval development has been completed. The third-instar maggot then leaves the host larva or pupa and enters the soil where a puparium is formed. Approximately 13 days are required to complete the larval development. In the laboratory the puparia were formed in the upper 2 in. of the soil. The parasite usually reaches the pupal stage within the puparium before July 1, and the species remains in this state until the following April or May. Usually only one third-instar maggot of *L. exul* issues from an individual host larva or pupa.

"*L. exul* apparently competes with several species of dipterous and hymenopterous parasites. From a small number of *M. americana* larvae which were parasitized by *L. exul* and *Comptosia concinnata* at about the same date *C. concinnata* was successful more often than not when competing with *L. exul*."

A synopsis of the Nearctic species of *Oscinella* and *Madiza*, based on a study of the types (Diptera, Chloropidae), C. W. SABBOSKY (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 707-728).—A synopsis of the blackflies of the genera *Oscinella* (formerly known as *Oscinis*, *Oscinosoma*, and *Botanobia*) and

Madiza (formerly *Siphonella*) is presented, which includes keys to the groups and species.

[Report of fruitfly investigations in west Africa], R. H. VAN ZWALUWENBURG (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 78-83).—The results of observations made during the course of a trip of investigation in west Africa from November 9, 1935, to July 28, 1936, are reported, the principal sources of fruitflies found in the various regions being considered, including Sierra Leone, Nigeria, Cameroun (Cameroons), and Belgian Congo.

The food of tsetse-flies (*Glossina swynnertoni* and *G. palpalis*) as determined by the precipitin test, C. B. SYMES and J. P. McMAHON (*Bul. Ent. Res.*, 28 (1937), No. 1, pp. 31-42).—The application of the precipitin test in determining the main food hosts of *G. swynnertoni* and *G. palpalis* is reported upon, the details being given in tables.

Summary of laboratory studies of *Anomala*, 1933-1935, R. H. VAN ZWALUWENBURG (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 25-32, fig. 1).—Studies of the Asiatic beetle, first recognized as a cane pest on certain areas in the Pearl Harbor district of Oahu and serious outbreaks of which were renewed in 1930 after several years of apparent control by natural agencies, are reported under the headings of *Anomala* coefficient, soil moisture, effect of humidity differences upon the incubation of eggs, life history, and miscellaneous observations.

Observations on the morphology and bionomics of *Serica brunnea* L., with notes on allied chafer pests.—I, The morphology of the larva of *Serica brunnea* L., W. F. JEPSON (*Bul. Ent. Res.*, 28 (1937), No. 1, pp. 149-165, figs. 8).—This contribution relates to one of the worst pests of forest nurseries in Great Britain, its status having been discovered by J. W. Munro in 1927 (*Ent. S. R.*, 59, p. 561).

Relation of gregarines to growth and longevity in the mealworm, *Tenebrio molitor* L., R. SUMNER (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 645-648, fig. 1).—In a study of the relation of gregarines to growth and longevity in the yellow mealworm conducted at Boulder, Colo., a total of 100 larvae and 20 adults was employed. Since the mealworms that contained gregarines grew more rapidly and had a lower mortality rate than the gregarine-free larvae, it is concluded that gregarine infestation is essential to normal growth and longevity in the mealworm. The gregarine infesting the mealworm was identified as *Gregarina steini* Berndt. Thyroid retarded growth more markedly in the noninfested than in the infested larvae and accentuated the mortality rate.

Effects of subzero temperatures on populations of western pine beetle *Dendroctonus brevicornis* Lec., F. P. KEEN and R. L. FUERNISS (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 482-504, figs. 5).—The habits of the western pine beetle, normal mortality, immediate effects of low temperature, modifying factors, subsequent effect of winter killing, subsequent reinfestation, effects upon predatory insects, and control considerations are presented in this contribution, the details of which are given in tables and charts. It was found in general that cold weather affects the insect enemies of the western pine beetle to about the same degree as the host.

Dusting to control strawberry weevil in Virginia, L. D. ANDERSON and H. G. WALKER (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 437, 438).—Control work by the Virginia Truck Experiment Station with the strawberry weevil, which especially during the past 3 yr. has been a serious pest of strawberries on the Eastern Shore of Virginia, is reported upon. Some of the fields observed

in the northern part of Accomac County are said to have had as high as 75 percent of the buds cut by the ovipositing weevils. Dusted plats were found to produce yield increases from 35 to 62 percent over untreated plats and to have but from 7 to 15 percent of the buds cut as compared with 39 percent of buds on the untreated plats. While the plats treated with sulfur-calcium arsenate dust had the least number of buds cut, they did not yield as well as the other treated plats because this material caused marked foliage injury. The sulfur-lead arsenate, lime-lead arsenate, and sulfur-derris dusts gave about the same weevil protection, but for some unknown reason the sulfur-derris treated plats fell slightly below the other two in yield. Heavy frosts and freezes on April 24 and 25 and later droughts reduced the yields about 80 percent below normal in all plats.

Since the common red spider is frequently a serious pest in this area, the sulfur-lead arsenate dust is preferred to the hydrated lime-lead arsenate dust because it gives protection against this pest. The sulfur-derris dust may be used to eliminate the danger of an arsenical residue in fields where early berries have set at the time of treatment.

Testing for resistance to American foulbrood in honeybees, O. W. PARK (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 504-512, figs. 13).—In summarizing work conducted at the Iowa Experiment Station (E. S. R., 77, p. 373), the results of the inoculation of 31 colonies are considered. "American foulbrood became well established in all 6 of the check colonies and in several of those supposed to be resistant. Of 25 supposedly resistant colonies tested, 7 were found apparently free from disease on September 28. Of these 7, all but 1 are known to have developed more or less American foulbrood following inoculation."

Some effects of temperature on the development and oviposition of *Microbracon hebetor* (Say), F. H. HARRIES (*Ohio Jour. Sci.*, 37 (1937), No. 3, pp. 165-171, figs. 2).—The approximate duration of the developmental stages of *M. hebetor* as a parasite of the Mediterranean flour moth has been determined at constant temperatures for the range of from 16° to 32° C. "The egg and nymphal periods combined require about one-third and the pupal period about two-thirds of the total preimaginal period. The data on development conform well to the thermal constant theory between 20° and 32°. Mean oviposition rates do not indicate a thermal constant but show a sigmoid relationship which shows only a slight difference in the rate of egg laying between 28° and 32°. The thermal constant for development has a value of 154 day-degrees, and the temperature characteristic for oviposition between 16° and 26° has a least squares value of 21,400."

Coccid-inhabiting parasites from Africa with descriptions of new Encyrtidae and Aphelinidae, H. COMPTON (*Bul. Ent. Res.*, 28 1937), No. 1, pp. 43-51, figs. 3).—This contribution from the California Citrus Experiment Station reports upon the classification of coccid-inhabiting parasites, obtained by the New South Wales Department of Agriculture, in Kenya and Uganda from August to October 1935. The forms considered represent seven genera, one of which, *Bothriophryne*, is erected, and seven species, of which five are described as new.

Improved control of red spider on greenhouse crops with sulfur and cyclohexylamine derivatives, C. C. COMPTON and C. W. KEARNS (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 512-522).—Studies of the toxicity of various compounds to the common red spider, infesting a number of greenhouse crops under laboratory, field, and greenhouse conditions, are reported.

"Great variations in the susceptibility of red spiders to certain sprays have been shown to be closely correlated with the species of plant infested. The

materials tested were Selocide (8 percent potassium-ammonium-seleno-sulfide), ammonium polysulfide, two organic thiocyanates (Lethane 440 and Loro), and a derivative of cyclohexylamine produced by the Monsanto Chemical Company, known as C. P. 100. All of these materials were found to be effective and safe when applied to certain plants. Rose proved to be the most difficult plant on which to obtain a satisfactory control of red spider without causing injury to the plant. Selocide and C. P. 100 have been the most successful in the control of red spiders infesting roses in the greenhouse. The use of karaya gum as an agent to increase the toxicity of red spider sprays has been found to be highly efficient in this respect."

Three possible mite vectors of the Dutch elm disease, A. P. JACOT (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 627-635, figs. 18).—*Moniezella arborea*, *Histiogaster fungivora*, and *Megninietta ulmi*, the latter representing a new genus, all collected in elm bark in lower Westchester County, N. Y., are described as new to science.

Two spinning mites attacking the incense cedar in California, E. A. MCGREGOR (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 770-775, pls. 2, fig. 1).—*Paratetranychus alpinus* and *Tetranychus libocedri*, which attack the incense cedar (*Libocedrus decurrens*) in Tulare County, Calif., are described as new to science. "It is not known which is the more serious, but together these two spinning mites are capable of considerable russetting and dropping of foliage of this magnificent Sierra conifer."

The anaerobic glycogen consumption in *Ascaris* females and males, T. V. BRAND (*Jour. Parasitol.*, 23 (1937), No. 1, pp. 68-72).—The glycogen content of the female of *Ascaris lumbricoides* from the pig was found to be a little lower than that of the male. The glycogen consumption is identical in both sexes during the first 24 hr. of starvation, but later on it decreases more rapidly in the female. This consumption appears to be much more independent of the glycogen content of the body than in free-living organisms.

A quantitative study of egg production in *Taenia saginata*, M. M. SCHAPIRO (*Jour. Parasitol.*, 23 (1937), No. 1, pp. 104, 105).—The results of counts made of the ova in four gravid segments from four different specimens of *T. saginata* are reported.

Fasciola gigantica, a liver fluke of cattle in Hawaii, and the snail, *Fossaria ollula*, its important intermediate host, J. E. ALICATA and L. E. SWANSON (*Jour. Parasitol.*, 23 (1937), No. 1, pp. 106, 107, fig. 1).—Contributing from the Hawaii Experiment Station, the authors record the snail *F. ollula* as the important intermediate host of *F. gigantica*, the common liver fluke of cattle in Hawaii.

ANIMAL PRODUCTION

[Livestock investigations by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 50, 51, 53-61, 129, 130, figs. 3).—Progress reports of animal nutrition and feeding investigations (E. S. R., 75, p. 530) include the value of cheese meal and various types of soybean oil meals as protein supplements in pig rations, by G. Bohstedt and J. M. Fargo; the necessity of fat as a supplement to a skim milk diet, by E. J. Schantz, C. A. Elvehjem, and E. B. Hart; and the discovery of a new essential dietary factor belonging to the vitamin B complex, by Elvehjem, C. J. Koehn, and J. J. Oleson. Poultry investigations yielded information on the value of alfalfa meal in winter laying rations, liver meal as a substitute for dried milk in chick rations, the vitamin D requirements of laying pullets, and productive longevity in chickens as an inherited trait, all by J. G. Halpin and C. E. Holmes; the nutritional balance

necessary to prevent slipped tendon in chicks, by L. E. Clifcorn, Elvehjem, Hart, A. C. Wiese, and Holmes; the value of soybean oil meal for poultry, by H. J. Doebeald, Halpin, and Holmes; and the relative efficiency of oats, wheat, and corn for prevention of gizzard lesions in chicks, by Halpin, Holmes, H. R. Bird, Oleson, Elvehjem, and Hart.

Efficiency of horses, men, and motors, S. BRODY and E. A. TROWBRIDGE (*Missouri Sta. Bul. 383 (1937), pp. 24, figs. 7*).—This is a popular presentation of the results of research previously noted (E. S. R., 76, p. 370).

The chemical composition and nutritive value of certain cereal hays as affected by plant maturity, J. SOTOLA (*Jour. Agr. Res. [U. S.], 54 (1937), No. 6, pp. 399-415*).—This contribution from the Washington Experiment Station presents data on the chemical composition of the dry matter of a number of cereal and legume plants in relation to stages of maturity and the weight relationship of leaves, stems, and heads; the chemical composition of whole plants, leaves, stems, and heads; the coefficient of apparent digestibility (as determined with lambs); and the relative palatability of Albit wheat, Pacific Bluestem wheat, Markton oats, and Horsford barley hays harvested at different stages of maturity.

In the young stages, the composition of the dry matter of the cereals was found to be practically identical with that of alfalfa and sweetclover, with the exception of calcium and phosphorus. As cereals approached maturity the stem-leaf-head ratio was shown to be a fairly reliable index of their nutritive value. There was a close association of crude fiber with stems; of total ash and calcium with leaves; and of phosphorus, crude protein, and nitrogen-free extract with heads. Based on the total digestible nutritive content of the various hays as determined by digestion trials and taking dough-stage Albit wheat as 100 percent, comparative ratings of 119.1, 116.8, 108.8, 105.7, 98.4, and 95.5 were indicated for ripe Horsford barley, medium-dough Horsford, medium Markton oats, ripe Albit wheat, milk-stage Albit, and medium-dough Pacific Bluestem wheat hays, respectively. In general the medium-dough stage of kernel maturity was most desirable for hay from these cereals, any benefits from increased digestibility past this stage being offset by shattering of kernels, leaf loss, leaching, and general plant deterioration.

The calcium and phosphorus contents of important New Mexico range forages, W. E. WATKINS (*New Mexico Sta. Bul. 246 (1937), pp. 75, figs. 8*).—The material used in this study includes samples of the important range forages collected in each county of the State at or near the end of the growth period (September and October) and other samples of these forages collected during February and March after they had been subjected to the wintering and weathering processes. Samples of 34 species of grasses and 22 species of browse plants have been analyzed. Data on the dry matter and the calcium and phosphorus content of the forages along with information on the type of country, character of soil, elevation, and precipitation are tabulated by counties. On the basis of these data State maps are presented indicating the general plant distribution and the areas in the State in which forage plants are markedly deficient in either calcium or phosphorus.

The effect of the ingestion of cottonseed oil before and after hydrogenation on the composition of the body fat of the rat, J. M. SPADOLA and N. R. ELLIS (*Jour. Biol. Chem., 113 (1936), No. 1, pp. 205-218*).—Continuing this line of investigation (E. S. R., 67, p. 61), four groups of six rats each were fed experimental rations over a 10-week period, at the end of which all rats were killed and the adipose tissue removed and analyzed for total fatty acids and the component fatty acids present. Group 1 (control) received an adequate

basal diet containing only a small amount of naturally contained fat, while the remaining groups received 5 percent of cottonseed oil in some form by replacement of an equal amount of dextrin. Group 2 received the nonhydrogenated oil, group 3 oil which was hydrogenated to reduce moderately the linoleic acid content, and group 4 oil which was hydrogenated for maximum reduction of this acid.

The normal acid components of the body fat were found to be myristic, palmitic, stearic, palmitoleic, and oleic acids. The ingestion of fats of varying degrees of unsaturation particularly affected the unsaturated acid fraction of the body fat, rats receiving cottonseed oil depositing more palmitic and stearic acids than those receiving partially hydrogenated cottonseed oil or the low fat diet. Ingestion of linoleic acid resulted in its deposition in the adipose tissue in amounts approximately proportional to the quantity ingested and accompanied by a decreased deposition of palmitoleic and oleic acids. The body fat of rats receiving either plain or hydrogenated cottonseed oil contained small amounts of arachidonic acid and a saturated acid of molecular weight higher than C_{18} . Isooleic acid in the ration was deposited in the body fat.

The digestibility of rations by cattle and sheep, E. B. FORBES, J. W. BRATZLER, A. BLACK, and W. W. BRAMAN (*Pennsylvania Sta. Bul. 339 (1937), pp. 30, figs. 12*).—This bulletin presents results of four series of digestion trials each with sheep and dairy cows. Rations for the four experimental periods for both sheep and cows consisted of machine-dried alfalfa and a concentrate mixture (1:1) air-dry basis in periods 1 and 2; period 3, machine-dried alfalfa and ground corn (1:2) dry-matter basis; and period 4, sun-dried alfalfa hay and ground corn (1:1) dry-matter basis. The plane of nutrition at which the sheep were fed was 1.03, 1.27, 1.41, and 1.16 percent maintenance, and for the cows 1.38, 2.72 (milking cows), 1.36, and 1.21 percent maintenance for periods 1 to 4, respectively. The experimental technics and the apparatus used for collecting excreta are fully described. Data are presented on the average digestibility of a corn meal-alfalfa hay (1:1) ration by steers fed at 6 different planes of nutrition (from 0.5 to 3 times maintenance), and comparisons were made with the digestibility of rations as determined for the above groups of sheep and cows.

With steers the digestibility of dry matter, organic matter, crude protein, carbon, and total energy-producing nutrients was highest at a maintenance level and was lower at half maintenance and at each level above maintenance. With cows the digestibility of the rations also diminished as the plane of nutrition was raised above maintenance. In general, sheep digested the rations more efficiently than the cows, except for crude fiber in periods 1, 2, and 4, where the rations contained a high proportion of roughage. In these instances crude fiber was more thoroughly digested by cows. It is concluded that the published average coefficients of feeding stuffs for ruminants, which in the main have been determined with sheep at low planes of nutrition, are several percent too high to apply to the full-fed milk cow.

Researches into sterility of cows in South Africa: The influence of (1) dry rations, (2) lack of exercise, and (3) lack of sunlight on reproduction in beef heifers and cows, J. QUINLAN and L. L. ROUX (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 6 (1936), No. 2, pp. 719-772, figs. 44).—From over 6 yr. of observation it is concluded that a dry ration of corn, wheat bran, and teff hay for 9 mo. and in addition silage during the remaining 3 mo. of the year gave very satisfactory results as regards growth, age at which sexual maturity was attained, and reproduction in beef heifers and cows.

The restriction of sunlight and exercise was in no way detrimental to the health, growth, or vigor of the cows and heifers, did not delay the onset of maturity, and tended to shorten the length of the dioestrous cycle and also the length of the period between calving and the first subsequent oestrous. Such environment did increase the average number of services required per conception, but did not affect the average length of the gestation period nor the average weight of the calf produced in comparison with animals having access to unrestricted sunlight and exercise. High condition had no ill effect upon either general health or reproductive processes. An extensive bibliography and numerous photographs and individual case records are appended.

Returns per acre in cattle feeding, P. GERLAUGH and H. W. ROGERS (*Ohio Sta. Bmo. Bul. 186 (1937), pp. 104, 105*).—This test was designed to compare the feeding value of a full feed of corn silage with a similar area of corn fed as corn-and-cob meal and bundle stover, with legume hay supplied in each ration in such amounts as the cattle would consume. Two lots of 16 yearling steers each and two lots of 16 steer calves each were used in the trial, one lot of yearlings and one lot of calves receiving each type of ration for 287 days. The average daily gains, total gains per lot, and market value of the cattle were very similar for the two types of rations. The feed cost per hundredweight of gain was somewhat in favor of the silage ration, and the amounts of gain on the cattle per acre of feed showed considerable advantage in favor of the use of silage.

Comparison of feeds for wintering steers in the northern Great Plains, W. H. BLACK and O. R. MATHEWS (*U. S. Dept. Agr., Tech. Bul. 565 (1937), pp. 10, figs. 2*).—In further studies on wintering steers at the Ardmore (S. Dak.) Field Station (E. S. R., 63, p. 761), experiments were conducted over five winter feeding periods using about 40 high-grade Hereford steers approximately 18 mo. of age in each trial. The rations fed included alfalfa hay 8 lb. and oat straw 4 lb. per steer daily for all five winters; corn silage 16 lb. and oat straw 4 lb. per steer daily during three winters; sorgo silage 13.3 lb. per steer daily during four winters; and wintering steers on the range with supplements of alfalfa hay, oat straw, sorgo silage, and cottonseed cake during two winters. The length of the winter feeding period ranged from 142 to 182 days.

The average gains per steer were 22, 13, 46, and 44 lb., and the average value of feed consumed per steer was \$3.11, \$0.96, \$7.89, and \$4.72 for the above respective rations. These data indicate that corn silage and oat straw was the most expensive and the least efficient ration tested, that sorgo silage was more efficient and also more economical than the alfalfa hay-oat straw ration, and that it was more economical to winter steers on the range with supplemental feeding when necessary than to carry them in the dry feed lot.

Comparison of feeds for fattening beef calves before and after weaning, W. H. BLACK and E. A. TROWBRIDGE (*U. S. Dept. Agr., Tech. Bul. 564 (1937), pp. 12*).—Continuing these studies at the Sni-a-Bar Farms, Mo. (E. S. R., 70, p. 663), this series of experiments compared the following concentrate mixtures for feeding calves from the time they were old enough to eat such feeds until weaning time and for fattening them in dry lot: (1) Shelled corn and cottonseed cake 8:1; (2) ground corn and cottonseed cake 8:1; (3) shelled corn, cottonseed cake, and alfalfa-molasses feed 8:1:1; and (4) ground corn, cottonseed cake, and alfalfa-molasses feed 8:1:1. These tests were conducted in 1931-32 and 1932-33. High-grade Shorthorn calves were used in each trial. Suckling calves averaging 77 days of age at the beginning of the trials were creep fed for 140 days.

The average total gain per head was 320, 312, 298, and 307 lb. and the average feed consumed per 100 lb. of gain was 186.5, 240.6, 203.7, and 233.3 lb. on rations 1, 2, 3, and 4, respectively. The larger and more economical gains of the calves fed shelled corn and cottonseed cake more than offset the slightly higher valuation of the calves getting shelled corn, cottonseed cake, and alfalfa-molasses. Grinding the corn significantly increased the cost of gain.

After weaning, these four groups were fattened in dry lot for 193 days on the same respective rations plus alfalfa hay and sorgo silage. There were no significant differences in the total gains of the four lots during this period. Either grinding the corn or adding alfalfa-molasses improved the palatability of the rations. Less concentrates were consumed per head and per 100 lb. of gain by the calves fed corn and cottonseed cake than by those receiving alfalfa-molasses in addition. The practice of grinding the corn, adding the alfalfa-molasses, or both, was not justified in these trials.

Fattening steer calves.—II, Quantity of supplement, P. GERLAUGH (*Ohio Sta. Bimo. Bul. 186 (1937), pp. 107, 108*).—In this, the second trial of this series (E. S. R., 75, p. 240), the same feed ingredients and plan of feeding were used, but the calves were of lighter weight, averaging at the start slightly over 340 lb. The results substantiate previous findings that 0.8 lb. of mixed protein and mineral supplement per steer daily in addition to a corn silage and hay ration is not sufficient for satisfactory gains. This statement applies to the lot fed at this level throughout the trial and also to the lots fed at this level for the first and third 12-week period of the trial, respectively.

Adding supplement to corn for calves on bluegrass pasture, III, P. GERLAUGH (*Ohio Sta. Bimo. Bul. 186 (1937), pp. 108, 109*).—Reporting another trial in this series (E. S. R., 75, p. 240), two lots of home-grown Aberdeen-Angus steers and heifers averaging 523 and 526 lb. for lots 1 and 2, respectively, were grazed on good bluegrass pasture for 168 days. Lot 1 received corn alone as a supplement and lot 2 received corn and cottonseed meal. The average daily gain per head was 1.53 and 1.87 lb. for lots 1 and 2, respectively, and the cost per hundredweight gain was somewhat in favor of the group receiving cottonseed meal.

Reducing the amount of corn and increasing the amount of legume hay in rations for fattening yearling steers, P. GERLAUGH and C. W. GAY (*Ohio Sta. Bimo. Bul. 186 (1937), pp. 105, 106*).—In this trial three lots of 12 yearling steers each were fed over a 264-day experimental period. Lot 1 received all the corn-and-cob meal and all the legume hay it would consume, lot 2 received three-fourths as much corn-and-cob meal, and lot 3 one-half as much corn-and-cob meal as lot 1, each receiving all the legume hay it would consume, and the steers in all three lots received a uniform allowance of 1.5 lb. of mixed protein and mineral supplement per head daily. The average daily gain per steer was 2.04, 1.83, and 1.65 lb., the feed cost per hundredweight of gain was \$9.34, \$9.36, and \$9.74, and the market appraisal of cattle per hundredweight was \$10. \$9.75, and \$9.25 for lots 1, 2, and 3, respectively. The final degree of finish of the cattle was very much in proportion to their daily gains.

Raising calves on wire floors, J. W. BARTLETT and H. H. TUCKER (*New Jersey Stat. Circ. 372 (1937), pp. 4, figs. 2*).—This circular discusses the advantages resulting from raising calves on raised wire-floored platforms, the most important of which are improved health, greater gains, and more rapid growth of the young calves and also material savings in labor and in bedding material. Instructions for constructing individual calf platforms 4 × 5 ft. in size and floored with $\frac{3}{4}$ -in. mesh wire cloth are presented. The estimated cost for material is about \$5.50 per frame.

Breeding and lambing rate: Length of gestation period of range ewes, D. W. CHITTENDEN and A. H. WALKER (*Natl. Wool Grower*, 27 (1937), No. 3, pp. 24, 25).—The Montana Experiment Station has analyzed the breeding and lambing records of 672 grade Rambouillet ewes bred to Hampshire rams and 800 bred to Rambouillet rams. During a 30-day mating season, 54.32 and 43.25 percent of the ewes mated to Hampshire and Rambouillet rams, respectively, were bred during the first week, 33.78 and 34.88 percent during the second week, and 11.9 and 21.88 percent during the last half of the period. Lambing extended over a 35-day period, with 29.61 and 25 percent of the ewes bred to Hampshire and Rambouillet rams, respectively, lambing during the first week, 42.41 and 40.88 percent during the second week, 22.47 and 24.5 during the third week, and 5.52 and 9.62 percent during the last two weeks of the lambing season. The gestation period averaged 148.61 days for ewes bred to Hampshire rams and 150.51 days for those bred to Rambouillet rams, indicating that the breed of the ram has some influence on the length of the gestation period.

Further observations on the milk of the Merino ewe, A. W. PRICE (*Austral. Jour. Expt. Biol. and Med. Sci.*, 14 (1936), No. 3, pp. 187–192).—Data are presented on the average composition of colostrum from Merino ewes and on the average yield and composition of milk from similar ewes at 2, 3, 4, 6, and 9 weeks after lambing, the data for the 3- and 9-week stages being reproduced from a previous report.⁴

Relative efficiency for growing lambs of the protein in rations supplemented by soybean-oil meal, linseed meal, or corn-gluten meal, J. I. MILLER, F. B. MORRISON, and L. A. MAYNARD (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 6, pp. 437–448, fig. 1).—The [New York] Cornell Experiment Station has conducted a series of nitrogen balance experiments to determine the digestibility and utilization of the proteins in rations in which soybean oil meal, linseed meal, and corn gluten meal were used as supplements to corn and timothy hay or corn and corn stover. In each trial eight wether lambs were employed, and the feeding of an experimental ration extended over a 10-day (or longer) adjustment period and a 10-day collection period. Timothy hay or corn stover made up 50 percent of the rations, and the proportions of corn and protein supplement were so adjusted that the entire ration contained approximately 10 percent of total protein.

In all trials the coefficients of apparent digestibility of the protein were very similar. The average percentage of total nitrogen stored was 21.2, 21.1, and 22.8 on the timothy rations and 17, 15.9, and 16.3 on the corn stover rations when soybean oil meal, linseed meal, and corn gluten meal, respectively, was the protein supplement. These results with growing lambs indicate that these three protein-rich feeds have approximately the same efficiency as supplements to a low protein basal ration of corn and timothy hay or corn and corn stover insofar as the utilization of the total protein in the ration is concerned.

Determination of the yield of raw wool from its density under pressure, R. H. BURNS and A. JOHNSTON (*Jour. Textile Inst.*, 28 (1937), No. 1, pp. T13–T20, figs. 2).—This article from the Wyoming Experiment Station presents preliminary results indicating that it is possible to predict the actual yield of raw wool from its density under pressure within a comparatively small margin. The apparatus for making the compression test is described, and its value as a tool for the wool grower and buyer is discussed.

The poultry-keeper's text-book, E. T. BROWN (*London and Melbourne: Ward, Lock & Co.*, 2. ed., pp. 320, [pls. 67]).—A revision (E. S. R., 51, p. 176) of a practical book for the poultry keeper dealing with the origin and classification

⁴ *Anstral. Jour. Expt. Biol. and Med. Sci.*, 12 (1934), No. 1, pp. 7–12.

of breeds, the theory of breeding and poultry keeping, and methods by which they may best be put into practice.

[**Poultry investigations in New Jersey**] (*New Jersey Stat. Rpt. 1936*, pp. 15, 16, 18, 85, 86, 88, 89, 92, 93).—The various investigations discussed include changing trends in egg production performance and mortality in egg-laying contests, the correlation between weight of eggs and weight of chicks at hatching, heavy hatching eggs as a means of flock improvement with regard to egg size, variations in eggshell color in a given strain of Rhode Island Reds, cross-breeding for poultry meat production, and a comparison of individual cages v. pen management of the breeding flock. Nutrition studies gave information reported on the vitamin A requirements of the laying hen and on the role of tryptophane in chick nutrition.

A criterion for testing the accuracy of trap-nest records, W. A. HENDRICKS (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 6, pp. 461-464).—This contribution from the U. S. D. A. Bureau of Animal Industry points out a weakness of the existing methods of testing the accuracy of trap nest records in poultry record-of-performance work in that there is a lack of information regarding the amount of variability to be expected under normal conditions. A new test is proposed which is free from this defect and might be used to supplement those tests in present use. This test involves the calculation of a statistic which, under normal conditions, is distributed in the same manner as the well-known χ^2 criterion of goodness of fit as applied to frequency distributions. The number of monthly inspections corresponds to the number of degrees of freedom which specifies the form of the latter distribution.

Use of artificial light for poultry, C. S. PLATT (*New Jersey Stat. Hints to Poultrymen*, 24 (1937), No. 4, pp. 4).—The stimulating effect of light on egg production is discussed, and suggestions are offered as to when to use artificial light and how to feed the flock receiving it.

Growth and feed standards for New Hampshire, A. E. TEPPER (*New Hampshire Sta. Circ. 52* (1937), pp. 8, fig. 1).—This circular sets forth tentative standards for normal weight, growth, and feed consumption for the New Hampshire breed of chickens. A chart is presented for estimating the spread or margin of profit to be derived from birds sold for meat purposes based on varying meat prices and varying feeding costs.

Distillery slop in chick rations, W. M. INSKO, JR., G. D. BUCKNER, J. H. MARTIN, and A. HARMS (*Kentucky Sta. Circ. 46* (1937), pp. 8).—In a series of experiments in which distillery slop was fed at varying levels in a growing ration for chicks, thin distillery slop proved unsatisfactory as a supplement to an all-mash ration. Three separate trials were conducted in which thick distillery slop containing from 8.5 to 9 percent solids and prepared from mash which contained approximately three times as much corn as other grain replaced approximately one-half, four-fifths, and all of the corn in the chick-growing ration. The slop was fed ad libitum, in separate containers, except for one lot where the slop was mixed with the mash in the proportion of 1 part of mash to 2 parts of the slop. In all cases the ration containing the slop produced birds of greater average weight at 10 weeks of age than those on the all-mash ration. The amount of slop required to replace 1 lb. of mash varied considerably in the different trials, averaging about 16 lb. in the first and 24 lb. in the third trial. Cooking and flavor tests with broilers showed individuals from all lots to be exceptionally tender and of good flavor. Birds on the all-mash ration and those which received mash mixed with the slop had a higher percentage of fat than birds receiving the slop ad libitum.

Alfalfa leaf meal as a source of vitamin A for growing chickens, B. W. HEYWANG and H. W. TYTUS (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 8, pp. 559-

569, figs. 3).—The first phase of this study by the U. S. D. A. Bureau of Animal Industry was directed toward devising a suitable vitamin A-deficient basal ration for chicks. Feeding trials established a ration consisting of white corn meal, wheat middlings, casein, pure dried yeast, ground limestone, steamed bonemeal, viosterol solution, and salt 64:15:10:4:3:1:2:1 as satisfactory for studying the vitamin A potency of various alfalfa products. In the second phase of the study feeding trials compared the vitamin A potency of Arizona, California, and Colorado sun-cured alfalfa leaf meals, California alfalfa powder, and California and Oklahoma dehydrated alfalfa leaf meal. Positive control rations variously contained fresh alfalfa, cod-liver oil, or fresh carrots, and the unsupplemented new basal diet served as the negative control.

It is concluded that the vitamin A potency of alfalfa leaf meals varied greatly, with about as much variation occurring between different samples of a given type as among the different types studied. As little as 1.5 percent of the best alfalfa meals in the ration supplied adequate amounts of vitamin A for good viability and growth, but it is recommended that not less than 5 percent of alfalfa meal of unknown potency be used in the chick growing ration. Evidence obtained indicated an increase in the vitamin A requirements per unit of feed with increasing age of the chicks.

The relation of the carotenoid pigments of feed to the carotenoid pigments of egg yolk, J. S. HUGHES and L. F. PAYNE (*Poultry Sci.*, 16 (1937), No. 2, pp. 135-138).—The Kansas Experiment Station has studied the relation between the amounts of the alcoholic phasic fraction (xanthophylls) and the petroleum phasic fraction (carotene and cryptoxanthin) of the carotenoid pigments in yellow corn, green barley, and dehydrated alfalfa in the ration of laying hens and the percentage recovery of these pigment fractions in the egg yolks. When hens were fed 10, 20, 30, and 40 g of yellow corn daily, 17.4, 21.4, 23.5, and 25.7 percent of xanthophyll fraction and 12, 6.4, 4.8, and 7 percent of the carotene fraction, respectively, were deposited in the egg yolk, although in the case of the latter the percentage deposited varied widely with different individuals. When yellow corn, green barley, and dehydrated alfalfa were fed at such levels as to supply approximately 1 mg of the xanthophyll fraction daily, 25.7, 15.8, and 15.7 percent of the pigment from these respective sources was deposited in the yolks, but only 2.6 and 2.5 percent of the carotene from green barley and dehydrated alfalfa, respectively, was so deposited.

Vitamin D requirements of growing chicks as affected by the calcium content of the ration, J. R. COUCH, G. S. FRAPS, and R. M. SHERWOOD (*Poultry Sci.*, 16 (1937), No. 2, pp. 106-108).—Chick-feeding tests at the Texas Experiment Station in which the calcium content of the rations varied from 1.31 to 1.71 percent and the vitamin D potency from 1.1 to 3.6 international units per 100 g of ration showed that with suitable percentages of calcium and phosphorus the vitamin D required depends on the quantity of calcium present. With rations containing from 1.51 to 1.71 percent of calcium, 3.6 international units of vitamin D per 100 g of ration proved adequate for the first 12 weeks of growth and normal calcification of the bones of chicks kept in the absence of sunlight.

Comparison of cod-liver oil and ultraviolet irradiation as sources of vitamin D for confined laying hens, R. B. NESTLER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 8, pp. 571-582, figs. 6).—The U. S. D. A. Bureau of Animal Industry has obtained data on three groups of Rhode Island Red hens over a 2-year period. These lots were constantly confined without access to sunlight, one group receiving 2 percent of cod-liver oil as a supplement to the basal diet, a second group receiving 15 minutes' irradiation daily with a carbon arc lamp,

and the third group receiving no vitamin D supplement. The basal diet contained 7.9 percent of ash, 3.2 percent of calcium, and 0.9 percent of phosphorus during the first year, and 11.7 percent of ash, 2.1 percent of calcium, and 1 percent of phosphorus during the second year, but otherwise was constant throughout the trial. The results are presented in tabular and graphic form.

Cod-liver oil gave better results in egg production, live weight, total weight of eggs per hen, weight of eggshells, and hatchability of fertile eggs than resulted from the ultraviolet irradiation, with both supplements giving markedly better results than the unsupplemented ration inadequate in vitamin D. More feed was consumed per hen but less per dozen eggs produced by hens receiving cod-liver oil than by the irradiated lot. The percentage of ash and calcium in the eggshell was similar on the two supplemented rations, but the percentage of phosphorus in the eggshells was less for the cod-liver oil group than either of the other two lots.

Relationship between yolk index, percentage of firm white, and albumen index. V. HEIMAN and L. A. WILHELM (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 7, pp. 551-557, fig. 1).—The Washington Experiment Station has determined the observed grade, albumin index, yolk index, and percentage of firm white on 100 freshly laid eggs and on three other similar lots of eggs subjected to 4, 8, and 12 days' storage, respectively, at 80° F. and a wet bulb reading of 78°. Average values for the various egg quality measurements for each of the four lots of eggs are presented, and correlation coefficients were determined between observed grade and each of the other three measurements for each lot separately and for the entire lot of 400 eggs. Yolk index, percentage of firm white, and albumin index each showed changes upon storage which were due to deterioration in interior egg quality. The albumin index showed a high correlation with observed grade of eggs at each step, whereas yolk index and percentage of firm white showed little, if any, relation to observed grade or to each other in the fresh eggs or in the eggs which had undergone the same degree of deterioration.

Constituents of wheat gray shorts which prevent slipped tendons. R. M. SHEERWOOD and G. S. FRAPS (*Poultry Sci.*, 16 (1937), No. 2, pp. 109-111).—In a series of chick-feeding trials at the Texas Experiment Station, the high degree of incidence of slipped tendons on a basal ration was not materially altered by replacing 20 percent of ground kafir in the basal ration with either the ethylene dichloride extract or the alcoholic extract of an equivalent weight of wheat gray shorts. However, replacing the kafir with an equivalent weight of shorts, the ash of that amount of shorts, or the residue from the extraction of shorts with either the ethylene dichloride or alcohol resulted in a very low slipped tendon index, indicating that the factor in gray shorts which prevents slipped tendon is not an organic substance, but is one or more of the mineral constituents of the ash.

Serum phosphatase in the domestic fowl. R. H. COMMON (*Jour. Agr. Sci. [England]*, 25 (1936), No. 3, pp. 492-508, figs. 4).—The serum phosphatase activity has been studied in (1) normal birds from hatching to maturity, (2) laying birds receiving vitamin D supplement in the ration, (3) laying birds receiving high and low calcium rations, and (4) rachitic chicks.

Normal laying hens and hens in a period of suspended egg production were found to have a higher and more variable serum phosphatase value than cocks, while pullets which had never laid showed values similar to those for cocks. Serum phosphatase in chicks rapidly increased to a maximum at from 10 to 12 days after hatching followed by a rapid decline to 3 weeks of age, beyond which there was a gradual decline until maturity in cocks and a similar

decline in pullets until the onset of laying. Administration of vitamin D concentrate did not reduce the range of variation of serum phosphatase in laying birds. The increase in phosphatase was much greater during laying for pullets receiving low calcium than for those on a high calcium intake level. Phosphatase values were greatly increased in rachitic chicks.

Fluctuations of calcium and inorganic phosphorus in the blood of the laying hen during the cycle of one egg, J. G. FEINBERG, J. S. HUGHES, and H. M. SCOTT (*Poultry Sci.*, 16 (1937), No. 2, pp. 132-134).—This is a report from the Kansas Experiment Station. The analysis of the blood serum of laying and nonlaying hens showed that the calcium level in each was relatively constant during the 26-hr. period of a single egg cycle. Analysis for inorganic phosphorus during a similar period revealed a marked rise in the blood phosphorus level of laying hens during the period of shell formation, while the phosphorus level in nonlaying hens was relatively constant throughout the period.

Effect of the calcium and phosphorus content of the diet of chickens on egg production and hatchability, H. W. TUTTS, T. C. BYERLY, N. R. ELLIS, and R. B. NESTLE (*Poultry Sci.*, 16 (1937), No. 2, pp. 118-128).—This contribution from the U. S. D. A. Beltsville Research Center reports three experiments in which diets containing different percentages of calcium and phosphorus were fed to laying pullets and yearling hens. In experiment No. 1 with pullets and experiment No. 2 with hens a constant phosphorus level of 1.2 percent was maintained, while calcium levels of 1.2, 3, and 5.4 percent were supplied both as calcium carbonate and as calcium sulfate. In experiment No. 3, including both hens and pullets, calcium levels of 1.2, 3, and 5.4 percent were fed at a phosphorus level of 1.2, while 0.9-, 2.25-, and 4.05-percent levels of calcium were fed at a phosphorus level of 0.9 percent, calcium carbonate being used as a supplement in all cases.

In the lowest levels of calcium intake the hens yielded more eggs than the pullets, but at the highest levels the pullets laid more eggs than the hens. In general, high calcium intake adversely affected the hatchability of eggs and increased embryonic mortality during the last 3 days of incubation, particularly in the case of hens' eggs. Calcium carbonate and calcium sulfate were equally satisfactory for egg production, but better hatchability resulted from use of the former. The level of phosphorus intake did not significantly affect either egg production or hatchability. The adverse effect of high calcium intake was more pronounced at the 0.9-percent phosphorus level than at the 1.2-percent level. A method is suggested for estimating the calcium required in the diet based on the phosphorus content of the diet, the feed consumption, and the potential egg-laying capacity of the chickens.

Hatchability as related to seasons and hour of laying, F. A. HAYS (*Poultry Sci.*, 16 (1937), No. 2, pp. 85-89, figs. 9).—The Massachusetts Experiment Station analyzed hatching records covering 20 yr. (1916-35) with the object of determining the relation of season to hatchability of fertile eggs and the possible relationship between the hour of laying and fertility of eggs, early embryonic death rate, late embryonic death rate, and the percentage of fertile eggs that hatch from hens and from pullets.

Eggs from hens gave a rather marked improvement in hatchability as the season advanced, while pullet eggs showed no change after the first two hatches. There was an increase in the proportion of eggs laid in the forenoon with advance in season, the proportion at all times being essentially the same for hens and pullets. Hour of laying was shown to have little or no effect on the above-named conditions.

A comparison of the glycine contents of the proteins of normal and chondrodystrophic chick embryos at different stages of development, A. R. PATTON (*Jour. Nutr.*, 13 (1937), No. 2, pp. 123-126).—This report from the [New York] Cornell Experiment Station is an extension and substantiation of work previously noted (E. S. R., 75, p. 680). Definite evidence was obtained that glycine is synthesized during the development of White Leghorn and Barred Plymouth Rock chick embryos. Chicks that died of chondrodystrophy during development contained less than normal amounts of glycine, although the relation between chondrodystrophy and the low value for glycine has not been established.

Effect of incubation temperature on time of death of chick embryo and relationship of energy metabolism to mortality, E. M. PRINGLE and H. G. BABOTT (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 6, pp. 465-468, fig. 1).—In this study, reported by the U. S. D. A. Bureau of Animal Industry, a total of 578 fertile eggs were incubated at 102° F. and 791 fertile eggs at 99°. The incubation was carried out in a respiration calorimeter, and all conditions were carefully controlled with relative humidity at 60-70 percent, oxygen at 21 percent, and carbon dioxide below 0.5 percent.

The results indicate that there are two critical periods of mortality at incubation temperatures of either 99° or 102°, during which approximately two-thirds of all mortality occurs. The first peak of mortality was reached on the third day of incubation at either temperature; the second period occurred shortly before the normal hatching time, the peak of mortality occurring on the nineteenth day at 102° and on the twentieth day at 99°. At both temperatures this peak in mortality occurred immediately after a sharp break in the heat elimination curve. A comparison of the energy metabolism and mortality curves of the growing embryo indicates an association between rate of change in energy metabolism and mortality.

Sexing day-old chicks, T. MURARI (*Agr. and Livestock in India*, 6 (1936), No. 1, pp. 63-65, pl. 1, figs. 2).—A description of the method of determining the sex of day-old chicks.

Light in relation to the experimental modification of the breeding season of turkeys, H. M. SCOTT and L. F. PAYNE (*Poultry Sci.*, 16 (1937), No. 2, pp. 90-96, figs. 2).—In a study at the Kansas Experiment Station, three lots of Narragansett female turkeys hatched in May were placed on experiment December 1. Lot 1 housed in an open-front poultry house received artificial lighting from 4:30 a. m. until daylight from December 1 to February 1 and in decreasing amounts until April 1, lot 2 was similarly housed without artificial lighting, and lot 3 remained in the open throughout the winter and breeding season.

The artificial lighting modified the reproductive cycle of the turkey, lot 1 starting to lay in January whereas the other lots produced no eggs until early March. There was little difference in the response of lots 2 and 3, indicating that proper housing exerted no influence on the sex cycle of the turkey. Subsequent trials showed that exposure to either white light or the longer wave lengths of red light stimulated early sexual activity, while the shorter wave lengths of blue light failed to exert such effect. The early ovarian activity is attributed to the increased light ration rather than to the lengthening of the feeding day. Four hours' artificial lighting during the normal period of daylight were without effect.

Dressing shrinkages of Bronze turkeys, S. J. MARSDEN (*Poultry Sci.*, 16 (1937), No. 2, pp. 112-117).—Tests at the U. S. Range Livestock Experiment Station at Miles City, Mont., indicate that the weight losses of Bronze turkeys

during overnight fasting averaged 3.34 percent of the live weight before fasting. The weight loss of young turkeys of both sexes and of all weights and grades during slaughtering, dry picking, and overnight air-chilling averaged 9.62 percent of the live weight after fasting. Little difference was noted between sexes, but large birds lost a smaller percentage than small birds and fat birds less than thin ones. Weight loss due to full drawing averaged 14.65 percent of the dressed and chilled weight in fat young toms and 15.39 percent in fat young hens. Weight loss due to killing, dry picking, chilling, and full drawing averaged 23.18 and 23.47 percent for young toms and young hens, respectively.

The dissection of a frequency distribution into two normal components, W. A. HENDRICKS (*Poultry Sci.*, 16 (1937), No. 2, pp. 129-131, fig. 1).—This note from the U. S. D. A. Bureau of Animal Industry is a critique of an article by Hays (E. S. R., 75, p. 829).

DAIRY FARMING—DAIRYING

Proceedings [of the] twenty-first and twenty-second annual meetings, western division, American Dairy Science Association (*Amer. Dairy Sci. Assoc., West. Div., Proc. Ann. Meeting*, 21 (1935), pp. [3]+95, fig. 1; 22 (1936), pp. [2]+84, figs. 8).—The proceedings, in mimeographed form, of the twenty-first and twenty-second annual meetings held at Portland, Oreg., October 6, 1935, and October 5, 1936 (E. S. R., 72, p. 830), are presented.

[Experiments with dairy cattle and dairy products in Connecticut] ([*Connecticut*] *Storrs Sta. Bul.* 214 (1937), pp. 14, 15, 19, 20).—Brief reports are presented on the effects of silage, succulence, and water in the dairy herd ration and sources of oxidized or cardboard flavor in milk.

[Investigations with dairy cattle and dairy products] (*New Jersey Stat. Rpt.* 1936, pp. 16, 17, 18, 42-46, 47).—Dairy cattle studies reported include the effect of a fish meal-sea kelp preparation on the reproductive process in the dairy cow; methods of winter feeding dairy heifers and their relationship to subsequent growth on summer pasture; the minimum milk requirements for raising dairy heifers; the value of grass silage, animal byproducts, and dehydrated molasses in the dairy ration; the loss of nutrients in molasses silage; grass silage as a means of growing more feed units per farm; and the carrying capacity of fertilized pastures. Breeding studies gave information on the consequences of inbreeding and outcrossing Holstein cattle, and color pigmentation in the skin and milk of Guernsey cattle.

With dairy products studies information was obtained on the influence of fatty acids and their triglycerides on the processing of dairy products, and the effect of processing on the physical and chemical properties of milk and its products, with special reference to the relation of the individual cow to the development of off flavors.

[Investigations with dairy cattle and dairy products by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 45, 46, 48-50, 51, 52, 131, 132, 149-158, figs. 2).—The following studies with dairy cattle are discussed: The effectiveness of dry rations for raising dairy calves, by I. W. Rupel and G. Bohstedt; the relative merits of the A. I. V. process and molasses for preserving legume silages, by W. H. Peterson, E. B. Hart, C. A. Elvehjem, Bohstedt, and Rupel; and the effect of age at first calving on subsequent milk production of dairy cows, by A. B. Chapman and G. E. Dickerson.

Nutrition studies yielded further information (E. S. R., 75, p. 535) on the factors responsible for summer milk excelling winter milk in nutritive value, the value of the juice from A. I. V. and molasses silage for fortifying winter

milk, and the differences in the nutritive value of summer-canned and winter-canned evaporated milk, all by G. O. Kohler, Elvehjem, and Hart.

Dairy products studies reported include improved methods for producing Swiss cheese starter cultures, by W. C. Frazier and P. R. Elliker; methods for salting brick cheese, by E. L. Byers and W. V. Price; suitable wrappers for processed cheese and the absence of a need for calcium citrate, by H. L. Templeton and H. H. Sommer; the suitability of certain low-cost equipment for the pasteurization of milk in cheese factories, by Price and Z. D. Roundy; factors affecting the stability of butterfat toward oxidation, by V. C. Stebnitz and Sommer; and a study of milk film characteristics and their effect on the utilization of ultraviolet radiation, by H. H. Beck, K. G. Weckel, and H. C. Jackson.

Persistency of production in Jersey cows and its practical application, L. COPELAND (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 151-158, figs. 4).—The author has compared the composite lactation curves of 20 class A Jersey records exceeding 1 000 lb. of butterfat with 30 class A 365-day and 30 class A 305-day records which failed to qualify for Register of Merit requirements. In the case of the high records the monthly milk or fat yield, after the maximum was passed, was approximately a constant percentage of the preceding month's production (range from 93.8 to 93.8 percent). With the low yields the percentage decline from month to month was also quite constant, although of a lower order than for the high yields until the last 2 mo. of lactation when the curve showed a sharper downward trend. Maximum yields of milk or butterfat gave little information regarding persistency, the cows with the same initial rate of yield varying greatly in persistency of production. Cows with a low total production reached a maximum rate earlier than cows with a high total production. Persistency appeared to be an inherited character. Heifers which, under normal conditions, failed to milk at least 8 or 9 mo. during their first lactation rarely developed into profitable producers during later lactations.

The value of artificially dried grass, silage made with added molasses, and A. I. V. fodder in the diet of the dairy cow and their effect on the quality of the milk, with special reference to the value of the non-protein nitrogen, S. J. WATSON and W. S. FERGUSON (*Jour. Agr. Sci. [England]*, 26 (1936), No. 3, pp. 337-367).—Continuing this line of investigation (*E. S. R.*, 76, p. 237), four lots of four cows each were fed over a 17-week continuous feeding trial. The rations included a control of roots, hay, and concentrates and experimental ones in which a considerable part of the concentrates were replaced by either artificially dried grass, molasses grass silage, or A. I. V. grass silage, the rations being so adjusted that each supplied equal amounts of starch equivalent and digestible crude protein for maintenance and milk production. The average composition and nutritive value of the various constituents of these rations are indicated.

A statistical analysis of milk and butterfat yields, butterfat percentage, and live weight changes showed no significant differences between the four rations. The value of the nonprotein nitrogen of the molasses and A. I. V. silages proved high at the levels fed, indicating that digestible crude protein is a better guide to the feeding value of the nitrogen of these feeds than either digestible true protein or protein equivalent values.

White fish meal for growth and milk production, C. F. MONROE, W. E. KRAUSS, and C. C. HAYDEN (*Ohio Sta. Bimo. Bul.* 185 (1937), pp. 46-52, figs. 3).—This is a report of the final experiment of a series (*E. S. R.*, 74, p. 338) on the use of fish meal and related feeds in dairy rations. Whitefish meal was com-

pared with linseed meal in the growing and milk-producing rations, the comparison being made on a protein equivalent rather than a weight basis. Two similar groups, each composed of 8 Jersey and 7 Holstein heifers, were started on experiment at 6 mo. of age and were carried on the test rations continuously up to the time of second calving.

No significant differences were noted in the rate of growth between the two groups of heifers, and the differences in milk and fat production during their first lactations in favor of the linseed meal ration were shown to be a matter of inherited milking ability rather than of feeding. Neither were there any consistent differences in birth weight of the calves from the dams on the two rations. However, calves from the fish meal group were more vigorous, the iodine contents of their thyroid glands were higher than for calves from the linseed meal group, and three cases of retained placenta occurred in the linseed meal group as contrasted with none in the fish meal group. It is concluded that whitefish meal compares very favorably with linseed meal on the basis of food nutrients furnished, and that fish meal is of special value in supplying iodine in the ration in regions where this element is deficient in natural feeds. This factor is considered to be of rather great importance in the producing ability, general health, and reproducing ability of dairy animals.

Gastric digestion of soybean flour, L. SHOPTAW, D. L. ESPE, and C. Y. CANNON (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 117-128, figs. 5).—This report from the Iowa Experiment Station describes a series of trials in which both calves with Pavlov pouches and calves with gastric fistulas were employed to study the gastric digestion of soybean gruel (1 part of soybean flour to 9 parts of water) and of a "fortified" soybean gruel ($\frac{1}{3}$ of total solids from skim milk) in comparison with that of whole milk and skim milk. In some cases calves were fed at 12-hr. intervals, others at 8-hr. intervals, and in a few instances food was passed directly into the abomasum.

The results were analyzed in terms of (1) the cubic centimeters of gastric juice collected by half-hour periods from the Pavlov pouches and (2) the free and total acidity of the gastric contents. The soybean flour mixture left the stomach more readily than the milk curds. The amount of gastric juice secreted was approximately the same in both the milk and the soybean gruel trials, indicating that the comparatively poor results obtained with soybean flour as a feed for young calves (*E. S. R.*, 75, p. 486) is not due to a diminished gastric digestion.

Second annual report of the dairy inspection service for the year ended December 31, 1936, C. W. ENGLAND (*Maryland Sta. Bul.* 408 (1937), pp. 377-387).—This report outlines the scope of the inspection service as provided in the recently amended Maryland Dairy Inspection Law, reviews the work of the service since its inception, and lists the plants operating under the provisions of the law and the testers licensed in 1936.

A simplified procedure for calculating weights of milk to their energy equivalent in milk of different fat content in accordance with the Gaines formula, A. E. PERKINS (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 129-132).—This note from the Ohio Experiment Station presents a set of factors for rapidly converting weights of milk of a given fat content to its energy equivalent weight of 4-percent milk in accordance with the Gaines formula (*E. S. R.*, 59, p. 467). Also a simple method is outlined for converting milk of any fat content to its energy equivalent amount of milk of any other basic fat content.

[Abstracts of papers presented at the 38th annual meeting of the Society of American Bacteriologists] (*Jour. Bact.*, 33 (1937), No. 1, pp. 25, 26, 90-94).—Abstracts of the following papers, dealing with subjects of significance in

dairying, are noted: The "Enterococcus" and "Lactic" Groups of the Streptococci, by J. M. Sherman, P. Stark, and E. S. Yawger, Jr.; The Gas-Producing Species of the Genus *Lactobacillus*, by C. S. Pederson; Surface Microflora of Limburger Cheese, by C. D. Kelly; Factors Affecting the Activity of Swiss Cheese Starter Cultures, by P. R. Elliker and W. C. Frazier; A Bio-physical Study of *Oospora lactis*, by J. R. Kurtz, L. B. Schweiger, and E. H. Parfitt; The Action of Air Under Pressure in the Oxidation of Acetylmethylcarbinol to Diacetyl in Butter Cultures, by C. R. Brewer, M. B. Michaelian, C. H. Werkman, and B. W. Hammer; and Reaction of *Escherichia-Aerobacter* From Milk on Eijkman Medium, and Productivity of Media Used in the Isolation of *Escherichia-Aerobacter* From Milk, both by M. T. Bartram and L. A. Black.

Standard methods employed for controlling the bacteriological condition of market milk, R. S. BREED (*Milk Plant Mo.*, 26 (1937), No. 1, pp. 44, 46; also in 2. Internatl. Cong. Microbiol., London, 1936, Rpt. Proc., pp. 183-185).—The author gives a brief account of the place occupied by the agar plate count, the direct microscopic count, and the methylene blue reduction test in the control of market milk in the United States and Canada, with information on trends in frequency of usage of the various methods from 1910 to 1935.

The use of formate-ricinoleate broth in controlling and preventing ropy milk epidemics, L. R. CHURCH (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 147-150).—Concluding that most outbreaks of ropy milk are caused by members of the *Escherichia-Aerobacter* group of bacteria, the author points out the value of formate-ricinoleate broth in detecting ropy milk bacteria, with particular reference to faulty plant sanitation and methods. Milk samples collected at various stages of plant processing and showing gas formation may or may not become ropy, but samples showing no gas will rarely develop ropiness when placed at from 60° to 65° F.

Streptococcus durans n. sp., J. M. SHERMAN and H. C. WING (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 165-167).—An actively hemolytic streptococcus obtained from milk powder and previously designated as *S. hemothermophilus* (E. S. R., 74, p. 543) has been studied further and is fully described. *S. durans* is suggested as a more appropriate name for this organism.

A study of the factors affecting the color of Guernsey milk with the Pfund color grader and the Wood colorimeter, H. H. TUCKER, J. W. BARTLETT, A. S. FOX, and K. O. PFAU (*New Jersey Stat. Bul.* 820 (1936), pp. 16, figs. 3).—In the course of this study color readings were made on individual milk samples from all Guernsey cows in the herd at the North Jersey Substation on one day of each month from September 1933 to November 1935. Fat determinations were also made on all samples. The herd received a 20-percent protein concentrate mixture throughout the trial, dehydrated alfalfa or mixed hay and corn silage during the winter months, and pasture in season. Color readings were made with the Wood colorimeter throughout the trial and also with the Pfund color grader during the last 18 mo. of the study. In addition, certain short-time studies were conducted to test the effects of certain feeds and feeding practices on milk color.

The mean monthly color values indicated that milk is relatively high in color from May to October and relatively low in color the rest of the year, with the lowest color values observed during the 2 mo. just prior to the time cows were turned on pasture. The feeding of 12 lb. of dehydrated alfalfa that had been stored for 6 mo. or 5 oz. of a carotene concentrate per cow daily during the late winter months had no effect on increasing the yellow color of the milk. The continued feeding of a ration of long field-cured hay, beet pulp, and grain resulted in a lower color in milk than was obtained from the dehydrated hay and silage ration.

Studies on the effect of stage of lactation showed that colostrum was highly colored and the most rapid drop in color occurred during the first 17 days after freshening, with a further gradual decline in the remainder of the first 30 days. The gradual decline in milk yield near the end of lactation was accompanied by gradual increase in percentage fat and in color. A coefficient of correlation of 0.6594 ± 0.0056 was found to exist between fat percentage and color as measured by the Wood colorimeter. Daily samples twice weekly were considered adequate for studying short-time color effects, and samples over a 24-hr. period once a month were sufficient for study color over a lactation period.

Factors influencing the formation of milk layer in bottled coffee cream, L. H. BURGWARD and J. L. MOONEY (*Milk Dealer*, 26 (1937), Nos. 4, pp. 40-42, 54, 56, 60, 62; 5, pp. 72-74, 76, 78, 80).—This study was undertaken at the Ohio State University in an effort to determine plant practices which might be adapted to the control of the formation of the milk layer in market coffee cream. Data are presented on the effect of (1) varying pasteurizing temperatures, separating temperatures, and fat content of the separated cream, (2) standardizing with either whole milk or skim milk, (3) varying the creaming or storage temperature, and (4) agitation of the cream, on the depth of the resulting milk layer. It appears that low temperature pasteurization, which is accompanied by an excess of soluble calcium salts, low temperature separation, high creaming temperature, and agitation of cream at low temperatures are factors causing excessive milk-layer formation, while inversely high pasteurization and separation temperatures and low creaming temperatures reduced the amount of the milk layer.

Changes in the acetylmethylcarbinol plus diacetyl content of butter, W. L. SLATTER and B. W. HAMMER (*Iowa Sta. Res. Bul.* 211 (1937), pp. 41-54).—The essential conclusions presented have been previously noted (E. S. R., 77, p. 97).

Studies on the chemistry of Cheddar cheese making, V, VI, R. M. DOLBY, F. H. McDOWALL, and A. K. R. McDOWELL (*Jour. Dairy Res.* [London], 8 (1937), No. 1, pp. 74-85, figs. 2; 86-91, figs. 2).—This series of studies has been continued (E. S. R., 76, p. 388).

V. Factors influencing the acidity and mineral content of cheese.—Data are presented indicating that the degree of acidity developed in a vat of milk at the time the whey is run has an important influence on the quality of the resulting cheese. High acidity at this stage caused increased mineral losses in the whey with a corresponding decrease in the mineral content of the cheese, exerted a detrimental influence on the body of the cheese, and increased its acid character. Experimentally increasing the lactose content of cheese also produced a more acid product at maturity, although some unfermented lactose was present in the cheeses 4 mo. after manufacture.

VI. Factors affecting the relation between lactic acid and titratable acidity in wheys.—Results obtained in this phase of the study indicate a close relationship between the titratable acidity and the lactic acid concentration in wheys obtained under various cheese-making conditions. Variations in the rate of acid development or in the lactose content of the milk did not significantly affect this relationship. In curd with low mineral content there was less complete neutralization of lactic acid, resulting in wheys showing a somewhat higher titratable acidity for the same lactate content. This condition, however, affected only the wheys coming off late in the cheese-making process.

The effect of certain metallic contaminants on the Cheddar cheese making process, C. R. BAENICOAT (*Jour. Dairy Res.* [London], 8 (1937), No. 1, pp. 53-60).—The additions of small quantities of soluble salts of copper, iron,

lead, zinc, aluminum, and manganese at such rates as to supply from 3 to 7 p. p. m. of the metals in milk prior to its use in Cheddar cheese making caused certain flavor and color defects in the mature cheese, although these were not evident when the cheese was graded at about 14 days after manufacture. The distribution of copper, iron, manganese, and lead between curd and whey fractions at different times during the cheese-making process is indicated. Discoloration in lead-contaminated cheeses appeared due to the formation of its sulfide, but in the case of iron and copper contamination discoloration was attributed to the atmospheric oxidation of a colorless metal: protein complex.

Studies in Cheddar cheese.—V, The effect of chemical substances on the ripening process, W. L. DAVIES, J. G. DAVIS, D. V. DEARDEN, and A. T. R. MATRICK (*Jour. Dairy Res.* [London], 8 (1937), No. 1, pp. 92-104).—Continuing this series of investigations (E. S. R., 76, p. 96), the effect of adding various chemical compounds to the curd on the rate of protein degradation during the cheese-ripening process has been determined. Eighteen compounds studied were classified as (1) substances stimulating or possibly stimulating the growth of lactic acid bacteria, (2) substances inhibiting or possibly inhibiting the growth of lactic acid bacteria, (3) substances affecting the H-ion concentration of the cheese, and (4) substances possibly affecting the flavor. The effect of these compounds in most cases was insignificant, cheese seeming to be remarkably stable. The chief factors affecting the rate of chemical ripening were the concentration of rennet, salt, and free water in the product.

Some factors influencing fat content in ice cream mix and the corresponding finished ice cream as determined by the Mojonnier method, J. J. JOHNSON and J. I. OXMOND (*Jour. Dairy Sci.*, 20 (1937), No. 3, pp. 159-164).—From a study of the causes of variation in the fat content it appears that improper handling of the ice cream samples, such as violent and continued agitation during melting which causes a fat and solid separation to take place, making it impossible to get a representative sample for analysis, is the largest contributing factor. Extreme agitation of the ice cream mix results in a concentration of the fat and solids in the top layer with a corresponding reduction in the lower layer of the mix. Condensation of moisture in the standardized mix and in the ice cream during freezing causes some fat reduction. The addition of color and flavor at the freezer causes a calculable fat reduction.

What should ice cream stabilizers do? V. C. STEBNTZ and H. H. SOMMER (*Ice Cream Rev.*, 20 (1937), No. 8, pp. 51, 52, 73, fig. 1).—This article from the Wisconsin Experiment Station deals primarily with the desirable qualities of sodium alginate as an ice cream stabilizer. It appears that this product possesses all the desirable properties of gelatin and has some distinct advantages, notably the production of uniform viscosity of the mix, faster whipping, and ice cream with more desirable melting qualities.

The new proposed procedure for making ice cream counts, A. H. ROBERTSON (*Ice Cream Rev.*, 20 (1937), No. 8, pp. 74, 78, 80, 84, 87, 88).—This report sets forth the plan and preliminary results of a cooperative undertaking to determine the relative efficiency of standard nutrient agar and tryptone skim milk glucose agar, each incubated at 32° and 37° C., for determining the bacterial content of ice cream mixes and ice cream.

VETERINARY MEDICINE

[Work with diseases and parasites by the Storrs Station] ([*Connecticut Storrs Sta. Bul.* 214 (1937), pp. 10-14, 15-17).—A brief review is given of the work of the year with diseases and parasites of livestock (E. S. R., 75, p. 252),

including infectious abortion and infectious mastitis (E. S. R., 76, p. 850; 77, pp. 396) of cattle; coccidiosis, paralysis (E. S. R., 76, p. 697), and laryngo-tracheitis and allied respiratory diseases of poultry; *Salmonella* infections in chicks (E. S. R., 76, p. 698); a disease of sheep caused by *Listerella* sp. (E. S. R., 77, p. 398); and parasites of the cottontail rabbit.

[Work in animal pathology by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 36-43, 81, 82, 148, 149, fig. 1).—Reference is made (E. S. R., 75, p. 537) to the value of sulfur in the prevention of coccidiosis (E. S. R., 76, p. 856) and to its failure to prevent blackhead, by C. A. Herrick and C. E. Holmes; further studies of mastitis, including control (by F. B. Hadley), relation of abnormal milk to (by E. G. Hastings), and effect of, on milk production; the failure of reactors to Bang's disease to transmit the disease to susceptible animals, by B. A. Beach and G. C. Humphrey; a study of red blood cells as an aid in the diagnosis of cattle diseases, by L. C. Ferguson; the toxicity of sweetclover hay; and the finding of a rapid growth of bovine and human types of tuberculosis bacteria to take place on a medium made from blackened potatoes, by J. R. McCarter and E. L. Tatum.

Selenium poisoning in fishes, M. M. ELLIS, H. L. MOTLEY, M. D. ELLIS, and R. O. JONES (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 4, pp. 519-522).—The results of a study on the toxicity of selenium poisoning in gill-breathing fishes, in which each of 150 goldfish were changed to fresh seleniferous water every 48 hr. and fed 3 standard pellets of shrimp meal immediately after being transferred, are reported.

A study of some acid-fast actinomycetes from soil, with special reference to pathogenicity for animals, R. E. GORDON and W. A. HAGAN (*Jour. Infect. Diseases*, 59 (1936), No. 2, pp. 200-206, fig. 1).—A study was made of a number of acidfast actinomycetes isolated from soils and vegetable material. "Although the proportion of actinomycetes that are acidfast undoubtedly is small, nevertheless it is obvious that such organisms are not rare in soil. A comparison of the cultural features of these organisms with one another and with those of actinomycetes isolated from lesions in man and animals shows that a close relationship exists between them. In fact we have not found any features that will serve to distinguish the 'pathogenic' types from the soil types. The character of the pigment formed will distinguish some strains from others; however, both pathogenic and soil types are usually pigmented, the colors ranging from yellow through orange to coral. One of the soil types was highly virulent for rabbits soon after it was isolated, producing in this species a disease which was not distinguishable from that produced by the pathogenic types. The soil types possessed little or no pathogenicity for guinea pigs, whereas the pathogenic types produced fatal infections."

The occurrence of *Bacillus necrophorus* agglutinins in different species of animals, W. H. FELDMAN, H. R. HESTER, and F. P. WHERRY (*Jour. Infect. Diseases*, 59 (1936), No. 2, pp. 159-170, figs. 2).—In the studies here reported *B. necrophorus* agglutinins have been shown to be present spontaneously in a large majority of normal-appearing adult horses, cattle, sheep, and swine. "In most instances the presence in cattle of hepatic abscesses containing *B. necrophorus* is not associated with an appreciable increase in the titer of *B. necrophorus* agglutinins. The serums of calves, rabbits, white rats, lambs, and human beings are essentially devoid of *B. necrophorus* agglutinins. There is no evidence that different species of animals are affected with distinct varieties of *B. necrophorus*. Serologically there exists a definite relationship between *B. necrophorus* agglutinins in the blood serums of sheep, swine, horses, and adult cattle in that they agglutinate antigens prepared from several strains

of *B. necrophorus* obtained from lesions in a single species. For the detection of obscure lesions associated with *B. necrophorus*, it would seem unwise to attribute diagnostic significance to the presence of *B. necrophorus* agglutinins in adult horses, swine, sheep, or cattle."

The animal reservoirs of brucellosis, W. A. HAGAN (*Cornell Vet.*, 27 (1937), No. 1, pp. 14-20).—The susceptibility of sheep, horses, dogs, and birds to *Brucella* infection is considered, an attempt being made to evaluate this hazard as a source of human infection. It is concluded that three degrees of susceptibility to *Brucella* infection may be distinguished among domestic animals. The contribution is presented with a list of 28 references to the literature. See also a previous note (*E. S. R.*, 77, p. 393).

Infectious catarrh of mice, I-III, J. B. NELSON (*Jour. Expt. Med.*, 65 (1937), No. 6, pp. 833-860, pls. 2).—The present contribution deals with the nature and etiology of a disease observed in Swiss mice at Princeton, N. J., which had not been previously described or at least not recognized as a distinct entity.

Part 1 (pp. 833-841) reports upon a natural outbreak of the disease, the mortality of which in a group of 75 naturally infected mice was 95 percent over a period of 11 mo. Part 2 (pp. 843-849) reports upon the detection and isolation of small Gram-negative cells resembling the so-called coccobacilliform bodies of fowl coryza which were regularly found in the nasal and middle ear exudate of mice naturally and experimentally infected with catarrh. A second organism cultivable in fluid blood media with the formation of compact clumps and similar to the X bacillus of chickens was also isolated from infected mice. Part 3 (pp. 851-860) reports upon the etiological significance of these bodies, the disease having been regularly produced in normal mice by the nasal instillation of primary tissue cultures.

Spontaneous encephalomyelitis of mice, a new virus disease, M. THEILER (*Jour. Expt. Med.*, 65 (1937), No. 5, pp. 705-719).—The characteristics of a filtrable virus obtained from mice found spontaneously paralyzed and showing lesions of encephalomyelitis are described. The virus is not pathogenic for rhesus monkeys, and no evidence of immunological relationship with the virus of human poliomyelitis has been obtained.

Direct transmission of human influenza virus to mice, T. FRANCIS, JR., and T. P. MAGILL (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 2, pp. 132, 133).—The authors have found it possible to establish infection with human influenza virus in mice through direct intranasal inoculation with throat washings obtained from patients acutely ill with influenza.

Hemorrhagic septicemia, J. B. TAYLOR (*South Dakota Sta. Bul.* 307 (1937), pp. 8).—A practical account of hemorrhagic septicemia met with in cattle, sheep, swine, and fowls.

The local points of defense and the passive transfer of acquired immunity to *Nippostrongylus muris* in rats, M. P. SABLES and W. H. TALLAFERRO (*Jour. Infect. Diseases*, 59 (1936), No. 2, pp. 207-220, figs. 3).—The authors studied the mechanism of acquired immunity to *N. muris* by comparing the migration and development of the parasite in normal and hyperimmunized rats at short intervals during the previously unstudied first week of the infection and by passive transfer.

"In actively hyperimmunized rats the worms were retained and killed, to a small extent in the skin and to a larger extent in the lungs; of those that migrated to the intestine many were delayed, and upon their arrival the majority not only failed to grow or produce eggs but failed to remain. . . . Passive transfer of immunity was obtained by giving intraperitoneal injections of serum from hyperimmunized rats in doses of 4.1, 4.5, and 6.0 cc. (per 100-g

rat) to rats at the time of cutaneous infection with 3,400 or 4,000 larvae. . . . The finding of stunted and immature worms in immune rats and the passive transfer of the immunity, together with the finding of a precipitate around and in the gut of worms in the skin and lungs of immune rats in preliminary histological studies, indicate that the immunity to *N. muris* is essentially a local immunity in strategically placed organs, i. e., in the skin, lungs, and intestine, and has to a large extent an antibody basis."

Serological reactions with a virus causing rabbit papillomas which become cancerous, I, II, J. G. KIDD, J. W. BEARD, and P. ROUS (*Jour. Expt. Med.*, 64 (1936), No. 1, pp. 63-96, pls. 2, figs. 2).—Part 1 of this contribution (pp. 63-77) reports upon tests of the blood of animals carrying the papilloma; part 2 (pp. 79-96), upon tests of the blood of animals carrying various epithelial tumors. A description is given of a method that has been devised for serological tests with a virus producing rabbit papillomas that become carcinomatous.

A complement-fixation reaction involving the rabbit papilloma virus (Shope), J. G. KIDD (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 612-614).—In this further contribution (see above) a complement fixation reaction with extracts of filtrates of papillomas containing infective Shope virus and antisera effective against the latter is described.

Studies on an epizootic in domestic rabbits caused by *Pasteurella cuniculicida*, F. D. MCKENNEY and J. E. SHILLINGER (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 755-768).—A report is made of an epizootic in domestic rabbits in which *P. cuniculicida* was isolated as the causative organism. "Three forms of the infection were recognized: (1) An acute, rapidly fatal, septicemic form; (2) a subacute nasal rhinitis form; and (3) a chronic type expressed by subcutaneous abscesses. Cultures from all three types were used in transmitting the disease, but the type produced depends on the individual resistance of the animal and not on the source of the infective material. There is no certainty that such transmissions can be repeated indefinitely."

p-Aminobenzenesulfonamide and antipneumococcal serum therapy in type I pneumococcal infections of rats, P. GROSS and F. B. COOPER (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 4, pp. 535-540, fig. 1).—In experimental work with pneumococcal infections (type I) of rats, the details of which are given in tables, it was found that in the relative dosages employed the efficacy of p-aminobenzenesulfonamide is as great as, if not greater than, that of the specific serum. The data obtained show that the best therapeutic results came from a combination of serum and drug, indicating that the two methods of treatment are synergistic.

An improved spiral glass electrode and vacuum tube potentiometer applied to the measurement of serum pH in experimental *Streptococcus* infections in rabbits, P. J. HAETSUCH (*Jour. Infect. Diseases*, 59 (1936), No. 2, pp. 183-199, figs. 9).—A description is given of an improved apparatus.

A preliminary report on the problem of the bovine skin-lesion tuberculin-reactor, A. ROBERTSON and N. H. HOLE (*Jour. Compar. Path. and Ther.*, 50 (1937), No. 1, pp. 39-57).—A preliminary report is made on a number of bovine skin-lesion tuberculin-reactors examined at the laboratory at Weybridge, England. The results of the examinations and a review of the literature have led to the tentative conclusion that the skin lesions are the most probable cause of the sensitization to tuberculin, and that the sensitization is not consistently greater for avian than for bovine tuberculins or vice versa; neither does the subcutaneous test appear to, afford a means of differentiating the skin lesions from true tuberculosis. "We admit the possibility of the lesions being due to

an atypical form of *Mycobacterium tuberculosis*. However, in view of the microscopical appearance of the organisms, certain histological features of the lesions, failure to infect laboratory animals, and failure to cultivate the organism, we are of the opinion that the acidfast organisms seen probably do not belong to the recognized pathogenic types, although they may be associated in a group sensitization." It is pointed out that the acidfast organisms may not necessarily be the primary cause of the lesions but be secondary invaders of a wound or abscess.

A list is given of 44 references to the literature.

Influence of host factors on neuroinvasiveness of vesicular stomatitis virus, I, II, A. B. SABIN and P. K. OLITSKY (*Jour. Expt. Med.*, 66 (1937), No. 1, pp. 15-34, fig. 1; pp. 35-57, fig. 1).—Part 1 of this contribution reports upon the effect of age on the invasion of the brain of young mice by vesicular stomatitis virus instilled in the nose; part 2 on the effect of age on the invasion of the peripheral and central nervous systems by virus injected into the leg muscles or the eye.

On the occurrence of copulation infection among cattle with infectious abortion, A. THOMSEN (*Jour. Compar. Path. and Ther.*, 50 (1937), No. 1, pp. 1-9).—Experiments conducted with 3 bulls and 15 heifers, besides 4 control heifers, are reported, the details being given in table form.

Brucella abortus in raw market milk, C. P. FITCH and L. M. BISHOP (*Cornell Vet.*, 27 (1937), No. 1, pp. 37-41).—The milk from 67 dairies selling raw milk to a municipality was tested by the Minnesota Experiment Station, the presence of *B. abortus* being demonstrated in 25.4 percent. When agglutinins for *Brucella* could be demonstrated in a 1:25 dilution in a test of raw market milk, living *Brucella* organisms could usually be found. In all, 112 strains of *B. abortus* isolated from cattle were typed, 4 of which were *B. suis* strains and 108 *B. abortus* strains. A list of 15 references to the literature is included.

Anaplasmosis in cattle, H. SCHMIDT (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 723-736, figs. 2).—Following a brief discussion of its nature and manner of transmission, the susceptibility, immunity, immunization, and treatment of anaplasmosis in cattle, based upon a review of the literature and work at the Texas Experiment Station, are considered.

In the course of immunization work it was observed that following the injection of carrier blood containing anaplasmata and piroplasmata the reaction to the former began from the third to the sixteenth day and the second reaction, due to anaplasmata, began anywhere from the seventeenth to the forty-eighth day, the longer period of incubation being exceptional. Of 309 animals inoculated from two different blood donors, 9 had a period of incubation of from 45 to 48 days, while in 187 animals the period of incubation ranged from 29 to 38 days and 17 had an incubation period of 17 days.

Tables are given which show (1) the period of incubation in a group of 19 2-year-old bulls inoculated on the same day, each with 1.5 cc of fresh defibrinated blood drawn from the same animal which harbored only anaplasmata, and (2) the survival period of *Anaplasma marginale* and *Piroplasma digeminum* in infected blood kept at room temperature and also at ice box temperature. Charts which show the temperature curves of 3 of the bulls are included.

Use of formalized anti-blackleg vaccine in calves [trans. title], L. DE BLIECK and J. JANSEN (*Tijdschr. Diergeneesk.*, 64 (1937), No. 10, pp. 513-519; *Ger., Eng., Fr. abs.*, p. 517).—On 51 farms infected with blackleg on which 290 bovines (nearly all calves) were inoculated once with 5 cc of formalized anti-blackleg vaccine, blackleg due to inoculation was not observed and none of the vaccinated animals contracted the disease. The authors conclude that formalized anti-blackleg vaccine is the best for use against this disease.

Hemorrhagic septicemia investigations: The significance of *Pasteurella bovisseptica* encountered in the blood of some Florida cattle, D. A. SANDERS (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 737-748).—Contributing from the Florida Experiment Station, the author reports that *P. bovisseptica* is frequently encountered at autopsy in the blood and internal organs of cattle in that State. Exposure of calves, yearlings, and cows to this organism by means of ingestion and nasal spray failed to produce septicemia. The organism was recovered from the nasopharynx of cattle showing no gross lesions 3 mo. following mild exposure by means of nasal sprays and from the frontal sinus 2 mo. following introduction by means of trephining. *P. bovisseptica* may be demonstrated in the blood and internal organs of cattle shortly after death incident to *Anaplasma marginale* infection and in the blood and internal organs of cattle autopsied following *Crotalaria spectabilis* poisoning. "*P. bovisseptica*, colon-type, and other organisms may frequently be isolated from the blood stream of cattle showing advanced symptoms of bronchopneumonia and pulmonary emphysema which [have] developed incident to railway transportation. Umbilical injections of *P. bovisseptica* in suckling calves produce symptoms and lesions of omphalophlebitis. *P. bovisseptica* produced acute and chronic *Pasteurella* infection in the crow (*Corvus ossifragus*) when the organisms were instilled into the nasal cleft or when the drinking water was contaminated. *P. bovisseptica* organisms encountered in these investigations were lethal for rabbits in amounts of 0.001 cc of a 24-hr. salts bouillon culture given intraperitoneally or when a drop of the whole culture was instilled into the nasal passage.

"The demonstration of *Pasteurella* in bovine carcass material of suspicious hemorrhagic septicemia cases and its virulence for rabbits cannot always be accepted as a criterion regarding the etiological significance of such organism. Realizing different degrees of virulence attributed to strains of *Pasteurella* under variable conditions, no evaluation is claimed for organisms other than those encountered and examined in these studies or for their action on animals under conditions other than those undertaken in the investigation."

Hemorrhagic septicemia (*Cornell Vet.*, 26 (1936), No. 1, pp. 51-56, 56-58; 27 (1937), No. 1, pp. 52-62).—In the first paper a report of a hemorrhagic septicemia outbreak in a herd after the use of bacterins and the successful handling of this disease in a small herd, together with a discussion of anaphylaxis following administration of antihemorrhagic septicemia biologics, is given by M. G. Fincher. In the second, W. J. Gibbons reports upon the occurrence and treatment of cases of hemorrhagic septicemia. In the third, Gibbons and Fincher report upon the occurrence and treatment of hemorrhagic septicemia in 7 herds of cattle. Of the 379 head of cattle in these herds, 55 were affected and 6 died. In the treatment of the disease the use of serum appears to have been beneficial. Homologous serum was the most effective.

A comparison of the microscopic test, Hotis test, and blood agar plate in detecting streptococci of mastitis in milk, C. S. BRYAN and E. D. DEVEREUX (*Cornell Vet.*, 27 (1937), No. 1, pp. 68-74).—In comparative studies at the Michigan Experiment Station the culture in blood agar detected an average of 89 percent of all milk samples that were shown to contain mastitis streptococci in the microscopic test, a description of which has been noted (*E. S. R.*, 73, p. 108). "Considering the results of the microscopic test as accurate in detecting the presence of mastitis streptococci, the 24-hr. reading of the Hotis test (*E. S. R.*, 76, p. 391) will detect from 52.8 to 64.3 percent of the composite samples positive in the microscopic test. The results of the 48-hr. reading of the Hotis test will detect from 62.2 to 71.4 percent of the composite samples

positive in the microscopic test. When quarter samples of milk are tested, the 24-hr. reading of the Hotis test will detect 64.3 percent and the 48-hr. reading will detect 78.6 percent of the samples positive in the microscopic test. The Hotis test gives rise to many suspicious reactions. These do not permit a definite determination of the presence or absence of mastitis streptococci. The results of the Hotis test are not constant on repeated testing of milk from positive or negative cows, the results remaining negative or positive in the microscopic test and blood agar plate during this time."

The reliability of selected tests for the detection of mastitis, A. O. SHAW, H. C. HANSEN, and R. C. NUTTING (*Jour. Dairy Sci.*, 20 (1937), No. 4, pp. 199-203).—An examination made by the Idaho Experiment Station of 518 samples of milk taken from 10 cows over a 14-day period, using tests to demonstrate the presence of streptococci in incubated samples, hemolytic bacteria, cell count, chloride content, and H-ion concentration, is considered to have demonstrated "(1) the presence of streptococci in 92.5 percent of the samples taken from cows giving abnormal milk, 36.6 percent of the samples taken from cows having mild chronic mastitis, and 7.1 percent of the samples taken from cows definitely free from mastitis, (2) the presence of hemolytic bacteria in 82.5 percent of the samples obtained from cows secreting milk abnormal in appearance, 25 percent of the milk samples from cows having mild chronic mastitis, and 1.9 percent of the samples taken from definitely negative cows, (3) the presence of cell in excess of 100,000 per cubic centimeter in 87.7 percent of the samples taken from cows secreting abnormal milk, 27.7 percent of the samples taken from mild chronic mastitis, and 5.8 percent of the samples taken from negative cases, [and that] (4) the tests using the percentage of chlorides and H-ion concentration were extremely unreliable in detecting cows suffering from chronic mastitis."

Chronic bovine mastitis and milk yield, G. C. WHITE, G. W. COUTURE, E. O. ANDERSON, R. E. JOHNSON, W. N. PLASTRIDGE, and F. J. WEIRETHER (*Jour. Dairy Sci.*, 20 (1937), No. 4, pp. 171-180, figs. 3).—A comparison was made by the [Connecticut] Storrs Experiment Station of the production of animals before and after the development of laboratory evidence of mastitis, some of the animals being in the early stages of infection while in others the disease was latent in character. In many cases no clinical evidence was observable during most of the mastitis reacting periods. The data obtained tend to show that a loss in yield may occur in the majority of cases during the incipient stage of the disease.

"In 240-day lactations of a group of 30 cows having a history both as mastitis free and mastitis positive based on the bromothymol blue test, the sediment test, the leucocyte count, and the shedding of organisms, there was a loss of 463 lb. of milk attributable to mastitis. In another herd of 22 cows there was a loss in yield of 425 lb. These reductions are between 4 and 5 percent and are not particularly significant. A loss in yield was manifested in about two-thirds of the individual cases. When only one quarter was positive there was no loss in yield. Such are usually incipient stages, and possibly also compensation in yield is made by the unaffected quarters. The loss, however, increased in magnitude with each additional quarter involved, amounting to about 15-20 percent with all four quarters positive. When the results were segregated for each diagnostic test it was found that for those reacting to the bromothymol blue test the loss in yield was 837 lb., and for those shedding *S[treptococcus] mastitidis* the loss amounted to 1,100 lb. per lactation. The loss in yield of sediment positives was 596 lb. and of leucocyte positives 573 lb. No effect on the butterfat percentage was observed."

Trichomonas disease of cattle (*Vet. Rec.*, 49 (1937), Nos. 8, pp. 211-223, 224, figs. 4; 9, pp. 247-256).—This contribution consists of a review of the literature, accompanied by a list of 77 references, and laboratory data by A. W. Stableforth and N. J. Scorgie and a description of the outbreak by G. N. Gould, including a report on the histological examination by E. G. White.

Human tuberculosis in cattle, N. PLUM (*Skand. Vet. Tidskr.*, 26 (1936), No. 12, pp. 645-667; *Dan. abs.*, pp. 666, 667).—Following a brief reference to earlier reports on the infection of cattle with human tubercle bacilli, cases are described in which cows after infection with human type tubercle bacilli apparently gave positive reactions to the intracutaneous tuberculin test. A report is made of a field experiment in which a human with plumonary tuberculosis (typus humanus) through stable contact sensitized all of the animals to tuberculin. Experiments in which animals were fed tuberculous expectorate are also reported.

The clinical examination of cattle for the presence of open tuberculosis as practised in the Ostertag method of tuberculosis control and eradication, G. B. BROOK (*Vet. Rec.*, 49 (1937), No. 10, pp. 279-292, figs. 18).—This extended account is accompanied by a list of 23 references to the literature.

The fundamental features of the struggle in Denmark against tuberculosis in cattle, N. PLUM (*Skand. Vet. Tidskr.*, 27 (1937), No. 4, pp. 157-172; *Eng. abs.*, pp. 169-172).—A report upon the control work in Denmark.

The nature, epidemiology, and control of sheep myiasis in Britain: A summary of our present knowledge, J. MACLEOD (*Jour. Compar. Path. and Ther.*, 50 (1937), No. 1, pp. 10-32).—This contribution reports upon the nature of sheep strike, the history of sheep myiasis in Britain, the bionomics of *Lucilia sericata*, the factors affecting the occurrence of strike, the types and development of strike, seasonal changes in strike incidence, and control measures.

Some important parasites of sheep from British Guiana, H. V. M. METIVIER (*Trop. Agr. [Trinidad]*, 14 (1937), No. 1, p. 4).—Brief notes are presented on the stomach worm (*Haemonchus contortus*), *Trichostrongylus instabilis*, *Monodontus trigonoccephalus*, and the nodular worm *Oesophagostomum columbianum*.

Bacterial infection as a sequel to Ixodes attack of lambs [trans. title], P. HELLESNES and F. V. HOLMBØE (*Norsk. Vet. Tidskr.*, 49 (1937), No. 2, pp. 41-50; *Eng. abs.*, p. 50).—A discussion of infection and abscess formation resulting from the attachment of ticks to lambs in several districts of west Norway, in which staphylococci, *Bacterium pyogenes*, and streptococci, including in one case hemolyzing streptococci, were isolated.

Infectious pleuro-pneumonia of goats in Palestine: Communicability to sheep, S. J. GILBERT (*Jour. Compar. Path. and Ther.*, 50 (1937), No. 1, pp. 33-38, figs. 2).—An investigation of an outbreak in Palestine is reported upon.

Further studies of diseases affecting moose, II, R. FENSTERMACHER (*Cornell Vet.*, 27 (1937), No. 1, pp. 25-37, figs. 5).—This contribution from the Minnesota Experiment Station reports upon the examination and study of 5 moose additional to the 18 previously noted (*E. S. R.*, 72, p. 694). The symptomatology, necropsy findings, histopathological examinations, blood studies, serological and bacteriological findings, experimental animal inoculations, and tick attachment experiments are reported upon.

Swine erysipelas, G. L. DUNLAP and R. GRAHAM (*Illinois Sta. Circ.*, 471 (1937), pp. 13, figs. 11).—A practical account of swine erysipelas, which, in both acute and chronic forms, has been recognized for many years in central and northern Illinois and has resulted in serious death losses in farm herds.

Active immunization against swine plague by formalized vaccine [trans. title], L. F. D. E. LOURENS and C. J. DE GIER (*Tijdschr. Diergeneesk.*, 64 (1937),

No. 8, pp. 398-411; *Ger., Eng., Fr. abs.*, pp. 409-411).—Laboratory experiments and the inoculation of some 35 000 pigs in the field led to the conclusion that a formalized vaccine for swine plague, prepared according to the methods employed in Japan, gives an immunity that is sufficient to restrict the damage inflicted by the disease to a large extent.

Variations in inorganic phosphorus and calcium content of the blood of horses, B. J. ERRINGTON (*Cornell Vet.*, 27 (1937), No. 1, pp. 1-13, figs. 2).—A report is made of a study of the inorganic phosphorus and total calcium in the blood serum of horses.

Complement fixation test differentiating 3 strains of equine encephalomyelitic virus and the virus of lymphocytic choriomeningitis, B. F. HOWITT (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 526-528).—It has been found that the complement fixation test may be employed in the differentiation of strains of equine encephalomyelitic virus and the lymphocytic choriomeningitis virus of C. Armstrong and R. D. Lillie.* Thus far the test has been specific for the homologous strains when strongly hyperimmunized serums were used together with a potent antigen.

Midwinter equine encephalitis, L. P. DOYLE (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 786-788, figs. 2).—A report upon the pathology of a case of equine encephalitis that occurred in Indiana in January, contributed by the Indiana Experiment Station.

Bacterial resistance in B-deficient dogs, S. B. and W. B. ROSE (*Jour. Infect. Diseases*, 59 (1936), No. 2, pp. 174-182, fig. 1).—When dogs, the diet of which was complete except for vitamin B, were inoculated with *Staphylococcus aureus* the results indicated that animals rendered partially deficient with respect to vitamin B are more susceptible to the deleterious effects of artificial infection with *S. aureus*. The surviving B-deficient dogs had positive blood cultures for a longer period of time (average 12.2 and 6 days) than the caloric control animals. The vitamin-deprived dogs lost approximately twice as much weight as the control animals during the first 10 days after infection. The mechanism of the action of vitamin B is unknown. In the present state of knowledge it appears that this vitamin acts through its influence in helping to maintain an optimum nutritive state of the tissues; the resultant better physiologic condition of the animal seems to be of some importance in overcoming an experimental infection.

Streptococcic infections in dogs.—I, "Acid milk", arthritis, and post-vaccination abscesses, H. J. STAFSETH, W. W. THOMPSON, and L. NEU (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 769-780).—In work at the Michigan Experiment Station evidence was found that infections rather than acid milk are responsible for early pup mortality. A streptococcus commonly encountered in the female genital tract and pups that have died of so-called acid milk is described as new under the name *Streptococcus canis*. The authors have found streptococci present in pus from abscesses resulting from antirabies vaccination.

Two cases of articular and muscular rheumatism or arthritis, apparently successfully treated with vaccine therapy, are described.

Some observations on the use of "Prontosil" in canine practice, A. WEICHER and H. L. SMITH (*Vet. Rec.*, 49 (1937), No. 15, pp. 452, 453).—In four of five cases in which *Streptococcus hemolyticus* was involved Prontosil appeared to have exerted a specific curative action.

[Work in poultry pathology by the New Jersey Stations], F. R. BRAUDETTE (*New Jersey Stat. Rpt.* 1936, pp. 89-91).—Reference is made (E. S. R., 75, p.

* Pub. Health Rpts. [U. S.], 49 (1934), No. 35, pp. 1019-1027, fig. 1.

691) to the diagnosis of poultry diseases during the year, including the occurrence of a thorny-headed worm, probably *Plagiorhynchus formosus*, in a white-throated sparrow, thought to be a new host, and *Haemoproteus columbae* in pigeons from South Carolina; investigations of infectious laryngotracheitis; a study of fowl paralysis; and paratyphoid infection in pigeons.

Internal parasites of poultry, R. GRAHAM, J. P. TORREY, J. D. MIZELLE, and V. M. MICHAEL (*Illinois Sta. Circ. 469 (1937), pp. 50, figs. 39*).—A compilation of information on internal parasites of poultry, including flatworms and roundworms and their control and prevention. An outline of primary and intermediate hosts, including illustrations of the adults of the intermediate hosts, together with a list of 28 references to the literature examined, follows.

Fowl cholera, F. R. BEAUDETTE and J. J. BLACK (*New Jersey Stas. Hints to Poultrymen, 24 (1937), No. 3, pp. 4*).—A practical account.

Coccidiosis in chickens, C. A. HERRICK and C. E. HOLMES (*Wisconsin Sta. Spec. Bul., 1937, Apr., pp. 7, pl. 1*).—A practical account of coccidiosis in chickens which includes information on the use of sulfur, a report upon which by the authors has been noted (*E. S. R.*, 76, p. 856).

Hemophile bacilli in the spleen of cases of fowl coryza [trans. title], C. A. VAN DOBBSSEN (*Tijdschr. Diergeneesk., 64 (1937), No. 5, pp. 225, 226-228; Ger. Eng., Fr. abs., p. 228*).—In two experimental cases of fowl coryza of rapid onset, the author succeeded in isolating *Hemophilus coryzae* (= *gallinarum*) from the spleen. Both fowls were in poor condition and anemic. In the bird that died, a fibrinous pneumonia was found at necropsy from which *H. coryzae* was isolated. No lesions were found in the anterior air passages. In the other fowl, which was killed, the author found no lesions aside from a mucopurulent rhinitis. By intranasal infection with the isolated strains the author was able to set up coryza of rapid onset in fowls.

The etiology of fowl paralysis, leukemia, and allied conditions in animals, VII, VIII, M. W. EMMEL (*Florida Sta. Bul. 306 (1936), pp. 42, figs. 9*).—This further contribution (*E. S. R.*, 77, p. 254) is presented in two parts as follows:

VII. *Hemocytoblastosis in chickens as induced by Salmonella aertrycke* (pp. 5-33).—It is pointed out that hemocytoblastosis as discussed in this contribution is a fundamental process in the development of many of the various pathologic manifestations resulting from infection by many species of the genus *Salmonella*. It also results from the injection of organ emulsions and filtrates of leukemic birds, commonly known as the transmission agent and referred to by some investigators as a filtrable virus.

"Experiments conducted to determine the effect of hemocytoblastosis on the growth curve show that in one instance 10 Barred Rock chickens, equally divided as to males and females, infected by the intravenous injection of a suspension of *S. aertrycke* when 3 weeks of age, averaged 696 g in weight when the birds were 10 weeks of age, as compared to an average weight of 924 g in the noninfected group. A repetition of this experiment with an equal number of Rhode Island Red chickens showed a difference of 190 g per bird in favor of the noninfected group when 10 weeks of age. Hemocytoblastosis has been diagnosed in 10 flocks of laying birds in which this process was the only pathologic manifestation occurring. Marked reduction in egg production was noted in all flocks. Scaly and more or less atrophied comb and wattles are the principal symptoms shown. A shorter incubation period results when birds are exposed to *S. aertrycke* during 'active' hemocytoblastosis. Birds showing 'recessive' hemocytoblastosis, or which have recovered from the process, show considerable immunity to subsequent infection by *S. aertrycke* as long as 6 mo.

"According to the conception of hemocytoblastosis advanced in this study, birds recover from this process in instances in which other pathologic manifestations do not develop. Many birds never show external symptoms of hemocytoblastosis. The rate of recovery depends in a large measure upon the intensity of the process. Recovery often requires as long as 3 to 6 mo. The course of hemocytoblastosis, once established, is dependent almost entirely upon the individual resistance of the bird."

VIII. *Hemocytoblastosis in naturally occurring cases of fowl paralysis and lymphomatosis, as well as in other birds from the same flocks* (pp. 35-41).—This contribution deals with hemocytoblastosis as concerned with naturally occurring cases of fowl paralysis and lymphomatosis, as well as in other birds from the same flocks in which these pathologic manifestations were observed.

"One hundred birds 6 to 52 weeks of age from 44 sources affected with fowl paralysis, 40 birds 14 to 98 weeks of age from 18 sources affected with lymphomatosis, 40 birds 6 to 33 weeks of age from 24 different flocks affected with 'light', anemia, and unthriftiness, and 75 apparently normal birds 6 to 28 weeks of age from 14 flocks in which fowl paralysis was occurring showed by total and differential blood counts that hemocytoblastosis was present. In general the degree of hemocytoblastosis varied to some extent in the different groups studied. Hemocytoblastosis was more pronounced in the group affected with light, anemia, and unthriftiness and less pronounced in the group affected with lymphomatosis. Birds affected with fowl paralysis and apparently normal birds associated with outbreaks of fowl paralysis occupied a place between these two extremes, hemocytoblastosis being slightly more severe in the group affected with fowl paralysis."

It is considered likely, in naturally occurring outbreaks of this group of diseases, that most of the entire flock become infected to some degree, although not necessarily sufficient to develop into one of the pathologic manifestations.

The importance of endotoxin of *Salmonella aertrycke* in the development of fowl paralysis, M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 749-754).—In connection with the work with fowl paralysis noted above, the author reports having found that the intravenous injection of endotoxin of *S. aertrycke* often results in transient but typical symptoms of fowl paralysis. "Birds show a progressive age resistance to the neurotoxic action of endotoxin. Repeated intravenous injection of endotoxin in chickens results in mild hemocytoblastosis, but repeated intravenous, intracerebral, or intraperitoneal injections will not result in fowl paralysis. Endotoxin in varying amounts in vitro inhibits agglutination and reduces the titer of *S. aertrycke*-immune serum and inhibits phagocytosis. *S. aertrycke* alone induced fowl paralysis in 22 of 108 birds 6 to 12 weeks of age, while the same number of causal micro-organisms plus 1 cc of endotoxin induced fowl paralysis in 53 of 105 birds of the same age. By the injection of endotoxin into baby chicks it was possible to predict, with 86.7 percent accuracy, the development of fowl paralysis when the same birds became 8 to 12 weeks of age and exposed to repeated intravenous injections of *S. aertrycke*."

A study of fowl paralysis, C. W. BARBER (*Cornell Vet.*, 27 (1937), No. 1, pp. 42-51).—Transmission experiments in which 434 chickens were used in an attempt to transmit fowl paralysis are reported upon, the details being given in tables. In four of the experiments reported the percentage of paralyzed birds in the inoculated groups was slightly higher than in the controls. "The highest percentage of paralysis in any one group was 16 percent. Other factors than percentage have to be considered. The mortality among the control groups was very high. The control groups were slightly smaller than the test groups.

The period elapsing between the time of the inoculations and the appearance of paralysis was exceedingly variable. Some birds became paralyzed 9 and 10 mo. after the inoculation. The results of these experiments do not definitely indicate the successful transmission of fowl paralysis."

A study of naturally infected field cases of avian typhoid, H. C. GAUGER (*North Carolina Sta. Tech. Bul. 53 (1937), pp. 63, figs. 8*).—Studies on seven fatal and eight carrier cases of avian typhoid contracted under natural conditions are reported, the details being given in numerous tables. "The external symptoms in the naturally infected field cases as received in various stages of the disease did not vary to any marked extent [from] external symptoms already recorded by other workers. It was possible to recover *S[almonella] gallinarum* from the blood stream with relative frequency during the fastigial or high fever stage of the disease. . . . Cases under study yielded *S. gallinarum* in droppings during the stages of fastigium, decline, and convalescence, indicating the possibility of the perpetuation of *S. gallinarum* infection of the premises by birds in these stages of the disease. In these studies *S. gallinarum* was present in relatively large numbers in the fluids of the eyes, posterior nares, and pharynx during the fastigial stage. . . .

"Evidence of possible egg transmission of fowl typhoid is shown by the recovery of the causative organism from three eggs laid by three carrier cases. Tube agglutination tests conducted on the blood of survivor cases started from 4 to 30 weeks after receipt and conducted for a period of from 34 to 41 weeks were positive in each case in a dilution of 1:25 or greater. In most instances the titer of the last test was less than in the first. Antigens of *S. pullorum* and *S. gallinarum* were used, and higher titer was obtained with the *S. gallinarum* antigen. The continued presence of agglutinins for the duration of the periods noted above was probably due to the focalization of *S. gallinarum* and not to reinfection. A whole blood or tube agglutination test with *S. pullorum* or with *S. gallinarum* antigen applied to survivors of a fowl typhoid outbreak within 2 or 3 mo. after the disease has subsided should probably remove a large percentage if not all birds which are in the carrier stage. Autopsy findings in fatal cases (acute and subacute infections) were similar to those described by other workers. . . .

"In addition to the recovery of *S. gallinarum* from sources noted while under study, the causative organism was isolated from the livers of fatal cases and from blighted ova or from ovarian tissue or from both sites in all survivor cases. Three distinct morphological types of *S. gallinarum* were identified in the strains studied: *S* (smooth), *rS* (slightly rough), and *RRRR* (strong rough). Organisms recovered from the liver of fatal cases were of *S* type. Strains from the blighted ova and ovarian tissue of survivor cases and from infected eggs laid by these cases were of *rS* or a mixture of *S* and *rS* types. A single strain recovered from the droppings of a survivor bird was of the *RRRR* type. The presence of *S* type organisms in fatal cases and *rS* and *RRRR* types in survivor cases suggests a relationship between virulence and morphology to the extent that the *S* type or organism is probably more virulent than either the *rS* or *RRRR* type. The probability of greater virulence in the *S* type than in *RRRR* type or *rS* type was further shown in pathogenicity tests in which four out of seven test birds inoculated with *S* type organism succumbed to infection within 14 days following inoculation, whereas only one fatality occurred in the test birds inoculated with *rS*, *RRRR*, or a mixture of *rS* and *S* types. In the latter instance the inoculum consisted of a mixture of *rS* and *S* types. The results of biochemical tests applied to the organisms studied were characteristic of *S. gallinarum*."

The recent turkey disease, H. P. JOHNSON and G. W. UNDERHILL (*South. Planter*, 96 (1935), No. 11, p. 28).—This contribution from the Virginia Experiment Station calls attention to a disease of turkeys in various parts of Virginia. In the first outbreak, observed in 1933, approximately 30 percent of the young turkeys in the affected area died during July and August, and in the summer of 1934 the same section encountered a recurrence of the disease, with an approximate loss of 40 percent of the turkey crop. By 1935 it had spread and appeared in various parts of the State where turkey raising is a major enterprise, the loss ranging from 10 to 50 percent of all the turkeys in such areas.

Affected birds lose their appetite, appear droopy, and have a tendency to lie down. "When disturbed they may move with difficulty, and when excited in the later stages, they may fall over, gasp, go into a coma, and, finally, die. Visible symptoms usually last for only 2 or 3 days, at which stage the birds either die or recover. No outstanding gross lesions have been found with the exception of slight inflammation of the duodenum. The birds are usually somewhat emaciated and appear anemic. The flesh is usually flabby and the musculature of a brownish color. Occasionally small hemorrhages and ulcers occur in the intestines." On microscopic examination of blood smears from affected birds a protozoan has been found, usually in large numbers. This is thought to be spread by an intermediate host, such as the simuliid or blackfly, commonly known as the turkey gnat, implicated by Skidmore in Nebraska in 1930 (E. S. R., 63, p. 825).

A blood disease of turkeys, E. P. JOHNSON and G. W. UNDERHILL (*South. Planter*, 98 (1937), No. 1, pp. 34, 39, fig. 1).—A practical account is given of the progress of work at the Virginia Experiment Station with the disease of turkeys noted above. In order to determine if certain flies of the genus *Simulium* are involved in the transmission of this leucocytozoon disease of the turkey, experimental houses were constructed and transmission experiments conducted which have shown the causative organism to be transmitted by a blackfly from infected to normal fowl.

Further records of the gizzard worm *Amidostomum anseris* in the State of Washington: Report of cases in wild waterfowl, A. O. JERSTAD (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 6, pp. 785, 786).—A brief report is made of cases of parasitism in certain species of wild waterfowl in Washington State that have come to attention since the earlier report of its occurrence in geese (E. S. R., 76, p. 108), in work conducted by the U. S. D. A. Bureau of Animal Industry in cooperation with the Western Washington Experiment Station.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the New Jersey Stations] (*New Jersey Stat. Rpt.* 1936, pp. 25-27).—The progress results are briefly presented of investigations on poultry houses, sweetpotato storages, the effect of tree roots on drain tile, and soil-saving terraces.

[Agricultural engineering investigations by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 18-27, figs. 4).—The progress results are briefly presented of investigations which are being conducted on the one-story dairy barn, by F. W. Duffee, S. A. Witzel, H. D. Bruhn, and E. C. Meyer; electric fences and a pumping system for treating alfalfa silage with molasses, both by Duffee and Bruhn; electric brooders and dual-wheeled tractor trailers, both by Duffee, Bruhn, and Meyer; and hay chopping and storage, by Duffee, Bruhn, Meyer, L. F. Graber, G. Bohstedt, B. H. Roche, and E. B. Hart.

Surface water supply of the United States, 1935, Parts 8, 10, 12 (*U. S. Geol. Survey, Water-Supply Papers* 788 (1937), pp. 197, pl. 1; 790 (1937), pp. 94, pl. 1; 792 (1937), pp. 166, pl. 1).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1935, No. 788 covering the western Gulf of Mexico basins; No. 790, the Great Basin; and No. 792, the Pacific slope basins in Washington and Upper Columbia River Basin.

Geology and ground-water resources of Duval County, Texas, A. N. SAYRE (*U. S. Geol. Survey, Water-Supply Paper* 776 (1937), pp. VI+116, pls. 8 figs. 3).—This report presents the results of a study made for the purpose of determining the availability and quality of ground-water supplies in the county and the relation of the ground water to the artesian waters in Brooks, Kleberg, and Willacy Counties.

Public Roads, [May and June 1937] (*U. S. Dept. Agr., Public Roads*, 18 (1937), No. 3, pp. [2]+53-67+[1], figs. 7; 4, pp. [2]+69-84+[1], figs. 7).—These numbers of this periodical contain data on the various highway projects as of April 30, and May 31, 1937, and on State motor-fuel consumption and tax receipts for 1936, and the following articles:

No. 3.—The Effect of Curing Conditions on Strength of Concrete Test Specimens Containing Burnt Clay Aggregates, by W. F. Kellermann (pp. 53-58, 61); and the Oliensis Spot Test Improved, by R. H. Lewis and J. Y. Welborn (pp. 59-61).

No. 4.—The Value of Petrography in Determining the Quality of Rock, by D. G. Runner (pp. 69-74, 77); and Vehicle Speeds on Connecticut Highways, by C. J. Tilden (pp. 75-77).

Curing hay, especially with reference to hay chopped into storage ([*Connecticut*] *Storrs Sta. Bul.* 214 (1937), pp. 17-19).—Results of seven trials in artificial drying of hay chopped into a small metal silo are briefly noted.

Improved poultry housing and equipment, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul.* 185 (1937), pp. 65-72, figs. 3).—This article offers some current ideas and suggestions generally applicable to specific plans for various types of housing and to older houses which may need to be modernized.

[Water and sewage research by the New Jersey Stations] (*New Jersey Stas. Rpt.* 1936, pp. 105-110).—Progress results are briefly presented of studies on the activated sludge process, chemical coagulation of sewage, electrodialysis of trade wastes, odor control of sewage, pathogenic organisms in surface water and sewage, industrial waste treatment, chlorination of sewage and activated sludge, and garbage disposal in sewage.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Storrs Station, 1935-36] ([*Connecticut*] *Storrs Sta. Bul.* 214 (1937), pp. 3-7).—Preliminary findings in a study of four eastern Connecticut towns are reported (1) as to tendencies since 1931 for the proportion of part-time farms to increase and for specialized farms to become more diversified and (2) as to types of part-time farms operated by newcomers since 1930. Some findings in a study of the marketing of fruits and vegetables in the Hartford, Bridgeport, and Waterbury markets are given as to size of weekly purchases and sources of supplies of stores, methods of selling by farmers, etc. Some preliminary findings and observations are also included in the study of the supply and transportation of milk in the State.

[Investigations in agricultural economics by the New Jersey Stations, 1935-36] (*New Jersey Stas. Rpt.* 1936, pp. 18-25).—Brief summaries are in-

cluded of the findings to date in studies of the costs of producing different farm products and the factors affecting economical production: the trends in types of farming in New Jersey as shown by farm management and organization studies; farm tax delinquency 1928-32, inclusive; the motor truck problem and its relation to marketing; and changes in vegetable and fruit marketing.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bmo. Bul.* 185 (1937), pp. 72-80; 186 (1937), pp. 97-104, 110, 111).—Included in Bulletin 185 is an article on Farm Business Summaries for 1930 to 1935, by J. I. Falconer and R. M. Isler (pp. 72-79), with a table based on 5,523 farm business records showing by counties by years the average cash receipts, cash operating expenses, cash investment expenses, and labor income per farm, the farms being grouped according to the chief sources of income. Bulletin 186 includes an article on Some Problems in Adjusting Land Use, by J. S. Cutler, A. H. Paschall, and G. W. Conrey (pp. 97-104), discussing the physical and economic factors affecting land use and the readjusting of land use on individual farms, and an article on Some Farm Management Factors Related to Soil Productivity Balance, by F. L. Morison (pp. 110, 111), with a table showing farm practices, yields, labor incomes, etc., in 1936 on 80 Wyandot County farms grouped in 5 groups according to the soil productivity balance maintained. The Index Numbers of Production, Prices, and Income, by Falconer (pp. 80, 112) (*E. S. R.*, 77, p. 123), are brought down through December 1936 and February 1937.

Current Farm Economics, [June 1937] (*Oklahoma Sta., Cur. Farm Econ.*, 10 (1937), No. 3, pp. 49-62+[2], figs. 7).—Included in addition to the usual price and purchasing power indexes are articles on Sources of Oklahoma Farm Cash Income, by L. S. Ellis and T. R. Hedges (pp. 51-53); Beef Cattle Situation, The Economic Situation, and The Agricultural Situation, all by T. R. Hedges (pp. 53-56, 60-62); and The Wheat Situation, by R. T. Klemme (pp. 56-60).

[Investigations in agricultural economics by the Wisconsin Station, 1935-36] (*Wisconsin Sta. Bul.* 433 (1937), pp. 1-13, fig. 1).—Included are the findings in studies (1) by B. H. Hibbard of taxes paid by farmers and city and village residents in proportion to their income; (2) by A. Hobson and G. R. Paschal of the significance of foreign trade to Wisconsin farmers; (3) by W. P. Mortenson of the use of fluid and evaporated milk during 1935 and 1936 by 1,029 families in Milwaukee, Kenosha, and Janesville, and the effect of the use of evaporated milk on the price of fluid milk; (4) by P. E. McNall of the effects of diversification on the labor incomes in 1935 of 1,260 farmers, and of the incomes in 1935 of 89 farmers with less than 40 acres of crop land; (5) by M. A. Schnars of the use of truck transportation by cooperative livestock shipping associations; (6) by H. H. Bakken and H. E. Larzelere of the reasons for the decline in the marketing of tobacco through the Northern Wisconsin Cooperative Tobacco Pool; (7) by O. J. Scoville, W. F. Musbach, and G. S. Wehrwein of the savings in public expenditures that would be effected by the relocation of land users not conforming to the zoning plan in Oneida County; and (8) by Hibbard and F. L. Garlock of the experiences of Wisconsin country banks from June 30, 1929, to June 30, 1935, with different types of loans.

Foreign Agriculture, [April and May 1937] (*U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr.*, 1 (1937), Nos. 4, pp. 155-206, figs. 3; 5, pp. 207-260, figs. 4).—Included in No. 4 are articles on Agriculture in Manchuria—Possibilities for Expansion, by W. Ladejinsky (pp. 157-182); and New Zealand Agricultural Policy, by A. T. Murray (pp. 183-200), and notes on German land ownership legislation tightened, France guarantees quality of French wines, new land

tenure law in Colombia, Argentina reduces production of wine grapes, and some recent Soviet decrees affecting agriculture.

No. 5 includes an address by Secretary H. A. Wallace before the National Council of American Importers and Traders, Inc., on An American Policy on Imports (pp. 209-216); an article on Germany's Capacity to Produce Agricultural Products, by N. Jasny (pp. 217-256); and notes on new self-regulation of agriculture planned in the Netherlands, Poland acts to check price advances, and collective contract for farm workers in France.

Rural land economics, 1936: Outstanding references relating to rural land economics, especially to the present national land policy (supplementing rural land economics, 1933-1935), compiled by O. CUMMINGS (*California Sta.*, 1937, pp. [1]-93).—This is a supplement to the bibliography previously noted (*E. S. R.*, 75, p. 709).

Economics of agricultural land use adjustments.—I, Methodology in soil conservation and agricultural adjustment research, R. SCHICKLE (*Iowa Sta. Res. Bul.* 209 (1937), pp. 337-423, figs. 16).—This bulletin describes the problems, procedure, and preliminary findings in a project entitled "a study of certain aspects of Corn Belt agriculture in order to determine suitable policy for production reduction", begun in March 1934 by the station in cooperation with the U. S. D. A. Agricultural Adjustment Administration with a view to suggesting desirable crop systems for Iowa that would economically maintain soil fertility and would be consistent with sound farm-management policies. The purpose of the bulletin is "to clarify objectives, evaluate basic assumptions, and interpret such concepts as soil conservation and land-use adjustment in the light of public policy" rather than to recommend solutions to the soil conservation and land-use problems.

The need for planning fundamental adjustments in agricultural production, the proper sphere for economic planning in agriculture, emergency character of the AAA programs, requirements for a long-time program in the Corn Belt, and research projects in agricultural adjustment are described. The characteristics of present farming conditions in Iowa, including present land-use patterns and crop systems, feed unit productivity of crops and pastures, commercial movements of feed grains, and animal units and livestock systems, and the economic problem of soil conservation, including some characteristics of soil erosion and depletion, levels of natural soil fertility, the "breaking point" of natural fertility, regional allocation of emphasis on conservation, methods of soil conservation, and soil conservation and farm income, are discussed. The adjustments in Iowa farming necessary to establish a maintenance agriculture, including adaptation of crop rotations to soil types, adjustments in the crop systems of the type-of-farming areas, effects of adjusted rotation on crop yields, feed production from the adjusted crop system, changes in livestock systems, and economic evaluation of the adjustment problems in the various type-of-farming areas, are also discussed. The objectives and basic assumptions of the regional agricultural adjustment project of the AAA are discussed and its results evaluated.

Types of farming and type of farming areas in Connecticut, I. G. DAVIS ([*Connecticut*] *Storrs Sta. Bul.* 213 (1936), pp. 144, figs. 22, map 1).—This study was based on 281 schedules obtained in the town of Woodstock in 1929, 1,802 in 11 other towns in the eastern highland section of the State in 1931, and 5,593 in 38 other towns in 1934.

The method of study is described briefly as follows: "In order to penetrate the obscurities created by attempting to describe a heterogeneous agriculture in terms of averages, it was decided to approach the problem of description no

longer from the standpoint of attempting to analyze or break down mass figures, but to approach it from the standpoint of the individual farm. By this method each individual farm would be described realistically in accordance with some uniform pattern or method of description. Similar farms would then be grouped in classes. A description of each class would be made not only in terms of typical farms but with due consideration for the class deviations from the mode. The approach would thus be from individual farms rather than mass statistics and the method would be that of building up groups of similar farms rather than in attempting to analyze totals or averages." With a few minor changes the method of farm classification is similar to that in Bulletin 191 previously noted (E. S. R., 71, p. 265).

"The bulletin contains five main parts: (1) A classification of the farms of Connecticut, showing the count of number of farms by classes and sub-classes; (2) a geographic study showing the type of farming areas for the State; (3) a description of the several types of farming found in Connecticut; (4) the utilization of the data of the study as a sample census of Connecticut agriculture; [and] (5) a history of type farming research in the United States and an appraisal of this study with relation to that history."

Types of farming in Utah, M. CLAWSON, W. U. FUHRMAN, G. T. BLANCH, and W. P. THOMAS (*Utah Sta. Bul.* 275 (1936), pp. 98, figs. 15).—"The specific purposes of this study are: (1) To locate and delineate the major type-of-farming areas of the State; (2) to analyze and describe the major types and some minor types of farming within each area; (3) to indicate the fundamental reasons for the principal differences which exist within and among these type-of-farming areas; and (4) to indicate, in a general way at least, the major problems facing farmers operating each type of farm."

Part 1 discusses the social and economic factors affecting Utah's agriculture, principal physical characteristics of the State, climate, soils, agricultural use of land, size of farm, land tenure, and distribution of types of farms.

The State is divided into four major types-of-farming areas, with four subareas under diversified-irrigated farms and ranches and three minor divisions under specialized livestock ranching. Part 2 analyzes the agricultural organization of each area and discusses the physical, climatic, economic, and social conditions; the relationship of crops, livestock, and range; the distribution of different types of farms, farm organization, etc.

Organization of a successful small farm in central west Tennessee, C. E. ALLRED, B. D. RASKOFF, and D. H. ESEY (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog.* 32 (1937), pp. [I]+II+38, figs. 14).—This report deals with the organization of a successful 50-acre farm in Crockett County. The data were gathered in a farm organization and soil conservation survey of 150 farms in the county made in 1935. An analysis is made of the extent of the farm business, receipts, expenses, cropping system and soil conservation practices, soil productivity, and efficiency factors of the farm. Comparisons are made with other farms in the survey.

How the Swiss farmers operate on the Cumberland Plateau, C. E. ALLRED, S. R. NESKAUG, and W. E. HENDRIX (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog.* 33 (1937), pp. [I]+II+30, figs. 14).—This is the study of a group of 16 small size but intensively farmed farms in Grundy County. Most of the operators were economically independent during the recent depression, while 72 percent of the population of the county was on the relief rolls at one time or another. The type of farming, farm practices, size of farm business, and farm receipts and expenditures of the group are analyzed and discussed.

Production requirements and costs on irrigated farms in Montana, P. L. SLAGSVOLD and C. HOWARD (*Montana Sta. Bul. 338 (1937), pp. 36*).—"The present study is intended to analyze the principal cost items in irrigated farming in Montana and to furnish basic data for the budget method of planning the farm business." It is based chiefly on farm production studies in Montana and other neighboring States where irrigation is of some consequence. Tables are included showing the machinery requirements with costs, depreciation and repair costs, average use, and average cost per acre for each type of implement for 80- and 160-acre farms in grain and hay and grain, hay, beans, and sugar beets; the average yields of different crops on such farms; the equipment requirements with costs, depreciation and repair costs, and costs per acre for 80- and 160-acre farms, seed and other supplies per acre needed for different crops; feed requirements and acreage equivalents for different kinds of livestock; and the labor and power requirements per acre in the production of sugar beets, alfalfa, small grains, potatoes, beans, and seed peas. Overhead, irrigation, drainage, and other costs are discussed.

Dairy herd organization and income on dairy farms, D. MEADE (*Maryland Sta. Bul. 404 (1936), pp. 207-220*).—Personal interviews were had regarding the organization and operation in 1932 of 90 dairy farms in 5 counties of Maryland, with dairy herds ranging from 9 to 51 head and averaging 22 head. The characteristics of the herds and management practices are described and analyzed.

The labor incomes per farm ranged from —\$2,005 to +\$2,036, averaging \$270.

"The most profitable farms produced more milk per farm, made better use of home-grown feeds, produced milk at a lower feed cost per 100, and made more efficient use of labor, resulting in a smaller expense per 100 lb. of milk or per pound of butterfat. Efficiency in production would seem to be more important than size of herd."

Factors indicating poor dairy practices were: (1) Average annual production per cattle unit was 4,500 lb. of milk and 180 lb. butterfat; (2) over 90 percent of the farms kept no records of milk and butterfat production of individual cows; (3) 29 percent of the sires were grades; (4) 85 percent of all pregnancies served only to freshen cows; (5) breeding records were kept on less than 50 percent of the farms; (6) Bang's disease was prevalent; and (7) 87 percent of all farms' cows were not fed a ration balanced in proportion to the productive capacity of the individual cows.

An economic study of dairy farms in Maryland, S. H. DeVault and A. B. HAMILTON (*Maryland Sta. Bul. 405 (1936), pp. 221-251, figs. 6*).—Farm management records were obtained from 184 dairy farms in 1931, 180 in 1932, and 176 in 1933. The farms are located in 5 counties where dairying was the chief enterprise and 2 in which dairying was a comparatively new enterprise. The areas and types of farms are described, and the organization and business are discussed and analyzed.

Receipts from milk and dairy stock represented 72.1 percent of the total receipts, poultry 9.7, other stock 1.3, truck crops 6.3, and wheat 5.9 percent. The average labor incomes were \$1,379 on the most profitable farms (25 percent), —\$349 on the least profitable farms (25 percent), and \$222 for all farms. Gross receipts, size of dairy herd, and milk sales per cow were the most important factors affecting profits. The low income farms had larger acreages of grain and hay and smaller acreages of pasture and truck crops. The high income farms had larger yields of crops and received \$136 more per farm from poultry, egg sales per hen being 58 ct. higher. The most profitable farms

purchased more feed but had a lower feed cost per unit of production. They also had a higher investment in machinery but expended less for labor.

Recommendations are made in regard to dairy organization and practices.

Cost of producing deciduous fruit trees in selected California nurseries (a progress report), R. L. ADAMS (*California Sta. Mimeogr. Rpt. 58 (1937), pp. [1]+10*).—This is a progress report on the findings in a study of the costs of producing seedlings and budded deciduous trees and the costs of marketing, made for the Deciduous Tree Board of the California Nurserymen's Association. Data were obtained from 15 nurseries producing 2,554,000 seedlings and 13 nurseries producing 2,307,000 dormant bud or second-year trees.

The average costs per tree for all nurseries studied were seedling year 2.5 ct., second year for trees graded as salable 3.6, and marketing 7.1 ct., and for the 10 nurseries for which complete data were obtained, 4.6, 4.2, and 8.7 ct., respectively. Costs varied greatly among nurseries. Discards of trees budded and subsequently graded as salable varied from 12.1 to 64.3 percent, averaging 39.6 percent in the individual nurseries. Trees graded salable but not sold varied from 2.6 to 24.4 percent, averaging 12.5 percent. Size of business had no significant effect on the cost of first-year trees, but the smallest nurseries were at a distinct disadvantage in the production of second-year trees. The cost of retailing trees averaged 7.3 ct. per tree as compared with 3 ct. for trees sold at wholesale.

What are production costs? R. L. ADAMS (*Amer. Nurseryman, 65 (1937), No. 12, pp. 3-5*).—With a few minor modifications, this is a reprint of the report noted above.

Farm tenure in Iowa.—III, The National Farm Institute symposium on land tenure (Iowa Sta. Bul. 357 (1937), pp. 297-376).—This third bulletin of the series previously noted (*E. S. R., 77, p. 265*) includes the following papers presented at the first National Farm Institute, held at Des Moines on February 19 and 20, 1937: What Has Happened to the Agricultural Ladder? by T. W. Schultz (pp. 301-308); The Farm Tenure Situation in the Cotton South, by W. W. Alexander (pp. 309-315); The Upward Spiral in Tenancy and Our Land Policies in Retrospect, by B. H. Hibbard (pp. 316-321); Influence of Business Booms and Depressions on Farm Income, by G. R. Davies (pp. 322-326); State and Federal Responsibilities in Improving Farm Tenure, by E. A. O'Neal (pp. 327-332); State Action on Farm Tenancy, by E. J. Meeman (pp. 333-340); Credit Policies That Will Give Us a Better Agricultural Ladder, by A. S. Goss (pp. 341-354); Farm Tenure From Standpoint of Institutional Owner, by G. S. Nollen (pp. 355-365); Stability for Agriculture, by H. L. Brown (pp. 366-371); and Iowa Farm Tenancy, by N. G. Kraschel (pp. 372-376).

Plantation operations of landlords and tenants in Arkansas, H. W. BLACKLOCK (*Arkansas Sta. Bul. 339 (1937), pp. 45, figs. 4*).—Information regarding 89 plantations in 9 counties of the State was obtained by interviews with landlords and tenants. The data are for the year 1934.

The average plantation included 1,306 acres, of which 53.4 percent was cultivated, 5.8 percent was idle tillable land, 9.8 percent pasture, 18.7 woodland not pastured, and 12.3 percent waste land. Of the cultivated land, 52.8 percent was occupied by cotton, 28.6 by corn, 10 by legume crops, and 7.8 percent by other hay crops. The landlord cultivated 40.8 percent of the land with wage hands. The average investment per plantation was \$71,224, of which 20 percent was borrowed. There was an average of 19 share croppers, 4 other tenants, and 4 wage hands per plantation. Of the credit supplied landlords, 60.3 percent of the long-term and 54.7 percent of the short-term credit was received

from local banks and 25.6 and 33.7 percent, respectively, from the Farm Credit Administration. The average gross cash income per plantation was \$10,774 and the net cash income \$4,503, or 8 percent on the investment.

Cropper farms averaged 16.3 acres, of which 12.3 acres were in cotton and 3.8 acres in corn. Share tenant farms averaged 29.1 acres, with 17.9 acres in cotton and 9.9 acres in corn. The average net incomes per family were share croppers \$284, other tenants \$425, and wage hands \$203. Croppers produced and consumed \$67 worth of products and share tenants \$131 worth.

The plantation commissary, length of tenure of and social contributions of landlords to tenants and wage hands, and the production of food for home use are discussed.

Some of the findings and recommendations were: In view of improved methods of farming and modern tools and machinery, tenant farms on the average should be larger; better results would probably be obtained in the production and preservation of foods if the work was done cooperatively rather than individually as at present; and because of low wage scales the use of better tools, equipment, and farming methods, and the flexibility in use of productive agents, the wage crop method in most situations gives the landlord better financial results than the tenant system.

"If the tenant system is continued, both the landlord and tenant would benefit by utilizing better tools, equipment, and machines on all acres. This would be made easier (1) if the tenant farms were larger to facilitate the use of improved farming methods and to keep the tenant's time more fully occupied, and (2) if provision were made for wage labor to assist tenant families during periods when the family labor is insufficient to hoe and pick the cotton."

In view of the relatively high rate of interest paid, the low return on investment, and the fact that interest payments take 27.1 percent of the net cash income, planters should provide more of their capital themselves. Longer term contracts with other provisions that would minimize the frequent shifting of tenants should be put into use.

Farm tenancy: Report of the President's Committee (Washington: Govt., 1937, pp. VIII+108, pls. 9, figs. 5).—This includes a report of the President's Committee, including findings and recommendations; a technical supplement dealing with farm tenancy in the United States, problems associated with tenancy, and some tenure programs of other nations; and a statistical supplement.

Cooperative marketing of sweet potatoes in Tennessee, C. E. ALLRED and B. H. LUECKE (Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 34 (1937), pp. [1]+III+41, figs. 7).—"The purpose of this report is to summarize the attempts made by Tennessee farmers and businessmen to handle their sweetpotatoes cooperatively from 1913 to 1930. An account of their failures, as well as their accomplishments, is given for the benefit of those who may wish to profit by the experience of others in this type of endeavor." The problems of sweetpotato marketing in Tennessee, the trend and geographical distribution, organization and method of financing, and functions attempted by and accomplishments of cooperative sweetpotato marketing associations in the State are discussed.

The authors found that the cooperative associations have rendered service by promoting commercial production of sweetpotatoes in sections adapted to that crop, providing storage where production was not sufficient to attract private commercial storage, making possible the assembling of the lots of small growers into carloads, and improving grading. Important causes of the failure of the associations were found to be overpromotion, small volume of business,

high annual cost in order to retire storage house indebtedness, insufficient operating capital, inefficient management, and competition of local markets.

Economic considerations in fixing resale prices of milk, J. M. TINLEY (*California Sta. Mineogr. Rpt. 57* (1937), pp. [1]+9).—This is a paper presented as testimony at a hearing held at Sacramento on March 24, 1937, to consider a bill to provide for enforcement of minimum wholesale and retail prices of market milk and market cream.

Regional differences in farm price of corn, Tennessee and United States, C. E. ALLRED, P. T. SANT, and C. M. SMITH (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 31* (1937), pp. [1]+IV+38, figs. 17).—This preliminary report includes and discusses tables, charts, and maps showing the average annual prices of corn in the United States by States, 1910-34 and 1930-34, and the average prices by counties of Tennessee, 1910-14 and from November 1929 to October 1935. Some data are included on regional variations in the prices of corn in other States. The effects of surplus and deficit production, transportation costs, production per corn-consuming livestock unit, productivity index, human consumption of corn, and other factors on regional prices of corn are discussed briefly.

Cotton prices in relation to cotton classification service and to quality improvement, L. D. HOWELL and J. F. HEMBREE (*U. S. Dept. Agr., Bur. Agr. Econ., 1937, pp. 42, figs. 7*).—This report is based on data collected in 24 selected local markets distributed throughout the Cotton Belt in 1933-34, 7 selected local markets in Texas in 1934-35, and 3 local markets in Texas in 1935-36. The markets included some in which there was little, if any, classification of the cotton before or at the time of sale by the growers, some in which more or less classification was made by the local buyers prior to sale by growers, and one in which sales were on the basis of classification of public classers licensed by the Secretary of Agriculture. The data are analyzed to show the grade and staple premiums and discounts reflected in prices paid to growers in the different groups of markets. The relation between average prices and average grade and staple length from market to market and from one period to another, the factors affecting grade and staple premiums and discounts, the influence of prices to growers on quality of cotton produced, and means of making desirable adjustments in the quality of cotton produced are discussed.

In 1934-35 about 18 percent of the central-market premiums for grades above middling and 59 percent of the discounts for grades below middling were reflected in the prices paid to growers in the markets without a classification service, and 85 and 128 percent, respectively, were reflected in the markets with classification service. The percentages of premiums and discounts for staple length were 7 and 47 percent, respectively, in the two types of markets. Grade and staple premiums and discounts to growers on the basis of the local buyers' classification averaged about 65 percent of those quoted in the central markets.

Average prices in different local markets reflected fairly accurately the differences in average quality of the cotton offered, so that the production of the higher grades and longer staples was generally rewarded on a community basis.

Statistical analysis of the annual average f. o. b. prices of canned clingstone peaches, 1924-25 to 1936-37, H. B. WELLMAN (*California Sta. Mineogr. Rpt. 59* (1937), pp. [1]+7, fig. 1).—Analyses are made of the average relations between f. o. b. prices of canned clingstone peaches and (1) total shipments of California canned peaches, (2) index of urban consumer's income in the United States, and (3) adjusted index of prices of canned fruits competing with canned peaches.

On the average a change of one million cases in total shipments of canned peaches was accompanied by a change in the opposite direction of 16 ct. a case in the average f. o. b. price of canned clingstone peaches; a change of 10 points in the index of urban consumers' income was accompanied by a change in the same direction of 45 ct. a case; and a change of 10 points in the adjusted index of prices of competing canned fruits was accompanied by a change in the same direction of 20 ct. a case.

Crops and Markets, [April-May 1937] (*U. S. Dept. Agr., Crops and Markets, 14 (1937), Nos. 4. pp. 69-88, figs. 2; 5, pp. 89-108, fig. 1.*)—In addition to the usual crop and livestock production reports and market reports, seasonal reports are included in No. 4 on cattle on feed, condition of important crops, farm labor supply and demand, farm real estate values, farm wage rates and index numbers, and grain stocks on farms April 1; and in No. 5 on condition of important crops, maple products, sugar beets and beet sugar, sugarcane, sugar, sirup, and molasses, tobacco, truck crops (acreage and production forecast), and wheat in interior mills, elevators, and warehouses April 1.

RURAL SOCIOLOGY

Some characteristics of rural families in three Michigan communities, C. R. HOFFER (*Michigan Sta. Spec. Bul. 283 (1937), pp. 22.*)—This study, comprising an analysis of data for 741 rural families in three selected communities in the State, showed that approximately two-fifths of the number had from one to two children, while 134 families had no children at all and 8 percent had six or more children.

In most instances the size of the houses appeared to be ample. Nearly two-thirds of the total number had seven or more rooms. The average number of rooms per person for the 527 rural farm families was 1.9 and for rural nonfarm (town) families 2.1.

In these families only about one-fourth of the husbands and one-third of the wives had attended high school.

The ways in which the leisure time of these families while at home was spent varied, although reading and listening to the radio occupied a large proportion of it. Three-fifths of these families had memberships in a church and one-half were represented in fraternal organizations.

Rural women and the Works Progress program: A partial analysis of levels of living, E. L. MORGAN, J. D. ENSMINGER, and M. W. SNEED (*Missouri Sta. Res. Bul. 253 (1937). pp. 29, figs. 9.*)—The data comprise records of 553 rural women in Works Progress Administration sewing rooms in 12 selected counties in the State. Two-thirds of the women were born on farms and an additional 20.6 percent were born in villages having less than 2,500 population. Their ages range from 15 to 78, with a median age of 41.5 yr. About one-fourth now reside on farms, while the others live in villages and towns. The residential distribution is thought to be in part a function of the location of work-rooms and in part the result of rural-urban migration.

All but seven of the women indicated that they were the principal economic heads of their respective families. The average length of time served as the economic head was 4.2 yr. Family income other than WPA wages averaged \$9.79 per month and was indicated by one-fourth of the women. There was an average of approximately three persons whose support was dependent upon these women. Only 6.7 percent had no dependents, but nearly one-third had no more than one.

It was indicated that 40.2 percent of the women had previously worked outside the home before they obtained employment under the work relief programs.

Work experience or skill was reported largely in the domestic and personal service occupations, with sewing most frequently reported.

Relation of size of community to marital status. D. SANDBERSON ([*New York Cornell Sta. Mem.* 200 (1937), pp. 74, figs. 32).—This study indicates that the proportion of persons 15 yr. of age or over who are married tends to decrease with the size of the community, while the proportion of persons who are single increases with the size of the community. The age at marriage, in the case of white persons, tends to increase with the size of the community for all classes except males on farms and in suburban cities of from 25,000 to 50,000 population. The proportion of broken homes, whether the result of divorce or of widowhood, also increases with the size of the community. The phenomena of marital status in incorporated villages are much more like those in small cities than those for the rural farm or nonfarm population.

Losses and gains of outstanding leaders in Tennessee. C. E. ALBRED and W. E. HENDRIX (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog.* 36 (1937), pp. [1]+11+21, figs. 10).—Natives of the State listed in *Who's Who in America* for 1930-31 number 507, or 3.29 persons for each 10,000 population in 1880. "This is lower than the average of the United States but higher than most Southern States." Those listed as born in Tennessee now live in 42 States, and 413 names are listed as living in the State, a net loss of 94 persons. The listings have come from 84 counties of the State. The State has suffered net losses of talent in all except 4 of the 13 occupational groups—educators, religious workers, natural scientists, and engineers.

Chinese rice farmers in Hawaii. J. W. COULTER and C. K. CHUN (*Hawaii Univ., Res. Pubs.* No. 16 (1937), pp. 72, figs. 15).—A historical statement concerning the Chinese rice farmers in Hawaii, including their agricultural operations and social and religious institutions.

Rural families on relief in Connecticut. N. L. WHETTEN, H. D. DARLING, W. C. MCKAIN, and R. F. FIELD ([*Connecticut Storrs Sta. Bul.* 215 (1937), pp. 76, figs. 8).—This report is the result of a cooperative study between the Federal Emergency Relief Administration and the station. It is a description of the relief population in 38 Connecticut townships, each with a population of less than 5,000, and distributed throughout the State to represent a sample of the rural population. The study is based upon 1,683 families, containing 6,057 members, who were on relief at some time during the period from February to December 1935. The information was collected every month from the local administrators of relief in each of the townships.

Some factors affecting social welfare in rural areas of Alexander County, Illinois, 1934. D. E. LINDSTROM ([*Chicago: Ill. Emergency Relief Comm., 1937*, pp. [2]+45, figs. 21).—In summarizing this study of Alexander County, made in cooperation with the Illinois Experiment Station, the following conditions stand out as being important and related to one another:

Although high hopes had been held in the early years of the development of the county for unusual growth and prosperity, on account of its location and resources, the total population, which included a high percentage of Negroes, had steadily declined during the last two decades. The rural population, on the other hand, had tended to increase slowly, particularly in the open-country areas. Approximately 51 percent of the total population were on relief in July 1934 and 40.4 percent in November 1934, when this study was made. About two-thirds of the land used for agricultural purposes was not producing properly, one-third needing better drainage and more efficient methods of farming, and the other third being cut-over forest land which should be returned to forests. The relief rates in these two areas were particularly high. Both business and

social conditions in the rural areas of the county were very poor. A great many projects were suggested as suitable for work relief, most of them being such practical types as improving roads, drainage, and school buildings.

Texas unemployable cases in the rural and town relief population, January 1936. W. C. HOLLEY ([*Austin*]: *Tex. Relief Comm., 1936, Rpt. 1, pp. [34], figs. 10*).—This report, made in cooperation with the Texas Experiment Station, presents an analysis of the unemployable case head data from a 100-percent sample of schedules. Of all heads surveyed, 89.5 percent were reported as handicapped by some type of disability.

Education of heads and children in the Texas rural and town relief population, October 1935 (28 sample counties).—Preliminary report, W. C. HOLLEY and C. E. ULLRICH ([*Austin*]: *Tex. Relief Comm., 1936, Rpt. 2, pp. [4]+13, fig. 1*).—Almost 18 percent of the heads of relief households had either never attended or never completed the first grade in school. Three out of 10 relief heads had completed only from 1 to 4 yr. in grade school. Less than 10 percent of all relief heads had completed grade school, less than 3 percent had completed high school and less than one-half of 1 percent had graduated from college. Children living in villages received more schooling than those living in the open country and in towns. The educational attainments of heads residing in towns were below those of heads living in the open country and villages. The study was in cooperation with the Texas Experiment Station.

The farm operator in the Texas rural and town relief population, October 1935 (28 sample counties).—Preliminary report, C. E. ULLRICH ([*Austin*]: *Tex. Relief Comm., 1936, Rpt., 3, pp. [45], figs. 8*).—More than one-half of the tenants and croppers studied were between 25 and 45 yr. of age, and more than 40 percent of the owners were between the ages of 45 and 65 yr. The most prevalent family size group of farm operator households was that of 4 to 6 members, with 212 families recorded, followed by the 1 to 3 members group, with 159 families. White farm operators had received considerably more formal schooling than other races. A small percentage of white farm operators led other races for sustained receipt of relief. In the aggregate, however, Negroes had been retained on relief rolls for longer periods than either whites or Mexicans. Also, Negroes received more material aid during the one month of this study than whites in every family size group but one, that of 7 to 10 members. Mexicans had been on relief rolls a shorter time and received far less relief per family member in October than whites and Negroes. Nearly 80 percent of all heads had been engaged in agriculture for 7 or more of the last 10 yr.

The study was in cooperation with the Texas Experiment Station.

The youth in the Texas rural and town relief population, October 1935 (28 sample counties).—Preliminary report, C. E. ULLRICH ([*Austin*]: *Tex. Relief Comm., 1936, Rpt. 4, pp. III+22, figs. 6*).—Out of 1,307 persons from 16 to 24 yr. of age in sample cases in the Texas rural and town relief population of October 1935, 556 were males and 811 were females. Fifteen percent of the white youths in the open country were heads of households, and 10.7 and 8.3 percent of the whites in villages and towns, respectively, were heads of households. Four out of five males and one out of every three females were either working or seeking work in October. Others were not eligible for employment because of school attendance, household duties, or physical disabilities. More than 12 percent of the group working or seeking work had no "usual" occupation.

The study was in cooperation with the Texas Experiment Station.

A study of family heads and other members in the Texas rural and town relief population, October 1935 (28 sample counties).—Preliminary report, C. E. ULLREICH ([Austin]: *Tex. Relief Comm., 1936, Rpt. 5, pp. IV+23, figs. 3*).—More than one-third of the heads of Texas rural and town relief households as of October 1935 were farm laborers and unskilled workers whose income was dependent upon periodic labor on the farm and in small communities. Negro relief families were more seriously handicapped by a lack of working members than were whites and Mexicans, having a high percentage of households with no employable members whatsoever and of households with only a single female worker each. As a general rule, the youthful members had received more schooling than members in the older age groups, while the superior educational advantages of whites over Negroes and Negroes over Mexicans were equally obvious. Farm workers required less relief than other workers, according to the number of months of assistance granted to each type.

The study was in cooperation with the Texas Experiment Station.

Fewer rural households on relief, G. W. HILL (*Wisconsin Sta. Bul. 438 (1937), pp. 13-15*).—A study of the rural relief situation in the State, conducted in cooperation with the Works Progress Administration, is reported. The data presented include occupations, reasons for relief, types of households, employment records, and reasons for leaving relief rolls in 1935.

Rural community buildings, D. E. LINDSTROM, W. A. FOSTER, and M. G. FULLER (*Illinois Sta. Circ. 470 (1937), pp. 58, figs. 2-4*).—This report deals with planning new types of community buildings, community needs, cost of buildings, financing construction and maintenance, control of community buildings, and articles of incorporation, constitution, and by-laws. A number of such buildings are illustrated and described.

FOODS—HUMAN NUTRITION

Food and the principles of dietetics, R. HUTCHISON and V. H. MOTTRAM (*London: Edward Arnold & Co., 1936, 8 ed., pp. XXVII+634, pls. 3, figs. 32*).—In this edition of this well-known volume, earlier editions of which have been noted (*E. S. R., 70, p. 270*), the material contained in the first three chapters on the nature, nutritive constituents, and relative values of foods; the amount of food required in health; and the influence of various conditions upon the food requirements has been revised with the help of H. K. Evans. Minor additions and alterations have been made throughout the whole book.

Dietetics simplified: The use of foods in health and disease, L. J. BOGERT and M. T. PORTER (*New York: Macmillan Co., 1937, pp. IX+637, figs. [77]*).—The major portion of this book, dealing with the use of foods in health and disease, is written by Bogert, and includes a brief discussion of qualitative and quantitative nutritive requirements, a rather full treatment of diet for normal conditions including family dietaries, and a nontechnical presentation of diets for diseased conditions. Therapeutic diets are considered as variations based on the normal diet. Separate chapters are devoted to food allergy, diets at different cost levels, and the adaptation of food to racial groups. In the treatment of diet and disease, each disease is presented along with other conditions which require diets of a similar nature rather than as a separate entity.

Porter has planned 30 laboratory lessons which are correlated with a similar number of chapters in the general text. The first 15 lessons deal with the cookery and service of different classes of foods, ranging from beverages and

cereals to infant formulas and moderate- and low-cost meals. The remainder consists of planning diets for normal and diseased conditions, together with the menu building and cookery required for carrying out such diet projects. The nutritive value of foods, weights and measures, and weight tables are contained in the appendix.

[Studies in foods and nutrition by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 130, 131, 133-144, 146, 147, fig. 1).—Included in this progress report are summaries of studies, several of which represent extensions of earlier work (E. S. R., 75, p. 564), by M. Johnson, H. Steenbock, and H. T. Parsons on the nutritive value of the proteins in raw and heated soybeans (pp. 130, 131); by E. Lease and J. H. Weber in cooperation with Steenbock on the effects of rancidity on vitamin A in fats (p. 133); by A. Arnold, C. A. Elvehjem, and E. B. Hart on the nature of the growth factor in liver (pp. 133, 134); by O. L. Kline, H. R. Bird, Elvehjem, and Hart on an improved ration for vitamin B₄ studies and the distribution of this vitamin in foods (pp. 134, 135); by W. C. Sherman and Elvehjem on the relation of vitamin B₄ to pyruvic acid metabolism (pp. 135, 136); by E. L. Hove, Elvehjem, and Hart on the function of zinc in the animal body (p. 136); by D. R. Borgen and Elvehjem, with the cooperation of K. B. McDonough and J. E. Gonce, on the question of a relationship between anemia and rickets (pp. 136, 137); by G. O. Kohler, Elvehjem, and Hart on the available iron in foods (pp. 137, 138); by M. O. Schultze, Elvehjem, and Hart on the relation of the copper content of the blood to hemoglobin formation and by Elvehjem, D. Duckles, and D. R. Mendenhall on the need of copper as a supplement to iron for the treatment of anemia in children (pp. 138, 139); by E. C. Van Donk, J. Semb, and Steenbock on sex differences in the storage of iron (pp. 139, 140); by H. H. Schneider and Steenbock on factors causing tetany (p. 140); by J. T. Lowe and Steenbock on the role of cereals in bone formation (pp. 140, 141); by P. H. Phillips and Hart on the use of aluminum salts to combat the effects of fluorine in the diet, and by Phillips on the effect of sodium fluoride on toxic goiter (pp. 141, 142); by J. Lease, Parsons, E. Kelly, L. Almon, and W. D. Stovall on egg white injury (pp. 142-144); by W. H. Peterson, Elvehjem, and P. Pavcek on factors influencing the vitamin B content of yeast (pp. 146, 147); and by Peterson, Steenbock, E. B. Fred, E. A. Prill, J. Berger, and D. W. Woolley on protein deficiencies of mold tissue (p. 147).

Experimental baking pans, C. F. DAVIS, L. E. LEATHEROCK, and H. W. PUTNAM (*Cereal Chem.*, 13 (1936), No. 1, pp. 113-118).—In this committee report, the 16 collaborators compared the tall- and low-form pans recommended for use in the official A. A. C. C. baking test procedure. Following preliminary tests, the dimensions of the low-form pans were changed to give the sides nearly the same pitch as the tall-form pan. This modified pan gave a definite increase in loaf volume and a product that more nearly resembled the commercial loaf in symmetry and proportion.

Report of the 1934-35 Pie Flour Committee, C. B. KRESS ET AL. (*Cereal Chem.*, 13 (1936), No. 1, pp. 104-112, fig. 1).—The committee made collaborative studies on 10 flour samples, which included baking tests using an artificial fruit filling of known acidity and a peach filling. It is recommended that in further investigations the test procedure should include pie with a filling such as the peach to determine shrinkage, toughness, and soaking of the crusts, the A. A. C. C. baking test with 3-hr. fermentation time, and viscosity comparisons to determine flour characteristics. Soft wheat flour of medium low viscosity gave the best test product.

Effect of stage of maturity of the snap bean on its composition and use as a food product. C. W. CULPEPPER (*Food Res.*, 1 (1936), No. 4, pp. 357-376, figs. 4).—In this contribution from the U. S. D. A. Bureau of Plant Industry, the entire bean, the hulls, and the seeds of Burpee Stringless Green Pod snap bean were analyzed at 5- or 10-day intervals from flowering until the beans were almost completely mature. The total solids in the entire bean decreased from the 5- to 10-day stage, then increased gradually to about the 20-day, and more rapidly to the 40-day stage. The hulls were low, with small changes, and the seeds high, with great changes in total solids during development. The sugar content was rather low, largely sucrose in the seed and reducing sugar in the hull, and in the entire bean rose to the 15- or 20-day stage and then decreased to the 40-day stage. The total nitrogen was high in the seed, low in the hull, and in the entire bean decreased slightly from the 5- to the 10-day stage and then increased slowly to about the 20-day stage, when a rapid rise occurred as a result of changes in the seed. The hull contained a small amount of nitrate, with none present in the seed. The tanninlike materials were higher in the seed than in the hull, with a rapid decrease in the seed content.

Cooking tests showed the 20- to 25-day-old beans to be best for table use, with an acceptable product in beans picked from the 10- to the 25-day stages. Canning tests with the same variety and Refugee Wax indicated that the best stage for canning was when the pods were 15 days old, with a fairly acceptable canned product possible from about the 10- to 20-day stage. The resistance to pressure appeared to be a little higher at the 5-day than at the 10-day stage, with a continued increase noted up to the 40-day stage, when it reached a point beyond the range of the pressure tester used. This resistance to pressure was very closely correlated with the percentage of insoluble solids present.

Dried egg-white. A. K. BALLS and T. L. SWENSON (*Food Res.*, 1 (1936), No. 4, pp. 319-324).—In this contribution from the U. S. D. A. Bureau of Chemistry and Soils a new commercial method is proposed for the preparation of dried egg white by acceleration of the enzymic decomposition in the presence of trypsin. The results of whipping and baking tests in which the enzyme-prepared egg white was compared with dried fermented egg white in sample angel food cakes were in favor of the enzyme-prepared product. The advantages of this new product are high sugar content, freedom from bacteria, and in general a closer resemblance to fresh egg white, together with the ease of preparation and saving of time.

Isolation and identification of an anaerobic organism producing gas in boiled beef. L. S. McCUNE and E. WHEATON (*Food Res.*, 1 (1936), No. 4, pp. 307-318).—The identification of the anaerobic gas bacillus *Clostridium welchii* present in raw meat as the cause of swells in a pack of commercially canned "roast" beef is recorded. The organism was not destroyed during the par-boiling process at a temperature of approximately 100°-110° C., and the production of gas during delay in the canning procedure caused the swelling of the cans. All cells were killed during processing so that the condition did not constitute a public health hazard. The toxin is not effective when administered orally.

The home canning of fishery products. N. D. JARVIS and F. P. GRIFFITHS (*U. S. Dept. Com., Bur. Fisheries, Invest. Rpt.*, 2 (1936), No. 34, pp. 11-16, figs. 5).—In this report new and improved procedures for the home canning of fish are presented. The use of the pressure cooker and of containers not larger than the No. 2 can and the pint glass wide-mouth jar, with composition gasket, is recommended. Recipes for fish dishes and sauces are included.

Microbiological studies of frozen pack berries, with special reference to effects of carbonation, J. A. BERRY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 224-226, fig. 1).—In this contribution from the U. S. D. A. Bureau of Plant Industry, further tests were made to determine whether there is a more rapid desiccation of the micro-organisms present in frozen pack berries at 15° than at -5° F., as reported in a previous study (E. S. R., 71, p. 560). The effect of adding carbon dioxide was studied, and tests were made to determine the keeping quality of the berries at temperatures above freezing after a period of freezing storage. Marshall strawberries, Cuthbert raspberries, and Evergreen blackberries were packed in No. 2 lacquered cans, 13 oz. of fruit and 5 fluid oz. of 50° Brix sirup per can. At the time of sealing, one-half of the cans were carbonated by the addition of about 0.5 g of solid carbon dioxide. Storage temperatures were -5° and 15° F. for the strawberries and -5° and 10° for the other berries.

Bacteriological examination of both carbonated and uncarbonated cans during storage showed that the destructive effect of 15° for 3 mo. was about equal to that of -5° storage for 12 mo. After 5 mo. of freezing storage yeast activity was noted in from 2 to 3 weeks in strawberries held at 70° and in from 7 to 14 days in raspberries and blackberries held at the same temperature. The presence of carbon dioxide failed to retard yeast growth. In airtight samples held at 40° in a household refrigerator after about 5 mo. of freezing storage the quality was maintained fairly well for about 4 weeks, with no increase in bacterial count, although a certain loss in texture occurred, particularly in the strawberries.

The physiology of nutritional requirements, A. M. BUTLER (*Jour. Amer. Dietet. Assoc.*, 12 (1936), No. 1, pp. 23-33, figs. 3).—The author reviews the present state of our knowledge and outlines the manner in which nutritional requirements may be met. Food substances are divided into those that supply the energy requirements of the body and those that supply the structural requirements. A chart is presented showing the individual factors with their chemical structures, fatty acids and hexoses in the energy group and amino acids, vitamins, inorganic elements, and water in the structure group. To determine whether the diet is nutritionally adequate, a method of planning a formula which will be comparable to mother's milk for the artificially fed infant is used as an illustration. The psychological and physiological reactions of the patient to the diet are important and must be considered by the dietitian.

Food consumption of Wisconsin relief families, M. L. COWLES (*Wisconsin Sta. Stencil Bul.*, 1937, Feb., pp. 27, figs. 4; abs. in *Wisconsin Sta. Bul.* 438 (1937), pp. 15-17).—A 2 weeks' study of the food consumption of 36 work relief, 31 commodity relief, and 36 nonrelief families in the land purchase area of Forest County, Wis., was made during the spring and early summer of 1933 for the purpose of comparing the character, costs, and adequacy of the dietaries of the commodity and work relief families with each other and with the dietaries of families in the same section not on relief rolls. The study also afforded an opportunity to compare the managerial skill of the families in the three groups and the extent to which purchased food was supplemented with home-produced.

The money values of the food consumed during the 2 weeks, including food furnished by the home garden or farm and valued at retail prices, were \$21.01 per household in the work relief group (paid in cash), \$16.78 in the commodity relief (paid in grocery orders), and \$20.21 in the nonrelief group. The proportions of total food costs furnished by the home garden or farm

were 41.6, 40.2, and 47.4 percent, respectively. Calculated in terms per adult male unit per day, the food costs for the work relief group, 28 ct., and the commodity relief group, 23 ct., were quite close to the cost per adult male of the adequate diet at minimum cost of Stiebeling and Ward, 26 ct., when adjusted to the same food price level. The cost of the diets of the nonrelief group, 30 ct. per adult male unit, although higher, did not approximate the Stiebeling and Ward figure, 42 ct. adjusted level, for an adequate diet at moderate cost. The distribution of the money costs among the different foods in the three groups showed considerable conformity with Stiebeling's suggested division to secure adequacy at moderate cost.

When judged on the basis of adequacy alone, the work relief diets ranked highest and the nonrelief diets lowest. The low average shown by the nonrelief diets is attributed partly to the fact that many nonrelief families were trying desperately to economize in order to keep off the relief rolls. Poor planning in the distribution of commodities is given as the chief cause of the inadequacy of the diets of the commodity relief group. In both relief groups there was little indication of any relationship between the size of the household and the degree of adequacy of the diet, probably because of the adjustments of food or money to the size of the family in the relief administration, but in the nonrelief families the inadequacies increased with the size of the family.

In general the adequacy of the diets was closely related to the total value or cost of the food consumed. Families whose diets were adequate in all of the nutrients studied were fed at a cost of from 32 to 38 ct. per adult male per day as compared with from 17 to 23 ct. per day for diets deficient in four or more nutrients. The higher cost diets, however, were well in excess of adequacy for all of the nutrients determined, showing that with better management fully adequate diets could have been secured at a lower cost.

In the final evaluation of the data from the standpoint of relief administration, the author concludes that "even a well planned and administered relief dietary may go wide of its mark of achieving nutritional adequacy if the family is lacking in the knowledge and skill necessary to administer it in the home. . . . Not only is emphasis needed on planning ahead for the spending of the food money in the market but on budgeting and planning for raising and home preservation of food at home. . . . Especial care and attention in securing dietary adequacy apparently should be given the families large in size. . . . Considerable leeway as to cost will have to be allowed in any diet having free choice rather than a controlled issuance in food. . . . Direct issuance of food has a considerable value, in addition to an advantage in cost, in lifting up food consumption to a certain minimum standard."

Metabolic studies of Eskimos in the Canadian Eastern Arctic, I. M. RABINOWITCH and F. C. SMITH (*Jour. Nutr.*, 12 (1936), No. 4, pp. 337-356).—Blood and urine analyses, respiratory quotient determinations, and metabolism studies were made on 46 Eskimos living in the Canadian Eastern Arctic region.

The average concentrations of nonprotein nitrogenous constituents of the blood were found to be higher than in other races. Although the chloride concentrations in the plasma of 34 subjects were high, the urine chlorides were extremely low. None of the urines collected contained glucose or acetones. The absence of glucose is in accord with the reported absence of diabetes among the Eskimos. Tests indicated that the Eskimos were unable to utilize large quantities of glucose when given in pure form. Respiratory quotients lower than 0.7 were found in 5 of 10 Eskimos in the fasting state and in 3 of 5 tests in 2 individuals after the administration of fat meals. The basal

metabolic rates were found to be high, the average of 10 subjects being +26 percent in terms of the Du Bois standard. According to the spectrographic examinations, the urines contained relatively large quantities of magnesium, normal quantities of copper, and no lead.

These findings are discussed in the light of the dietary habits and customs of the Eskimos in this region. The rarity of rickets among these people appears to be due to the long periods during which the infants are breast-fed and the fact that the vitamin D content of seal oil is said to be equal to that of the best cod-liver oil.

The basal metabolism of Chinese in Szechwan, L. G. KILBORN and F. G. BENEDICT (*Chin. Jour. Physiol.*, 11 (1937), No. 1, pp. 107-126).—The basal metabolic rates of 54 Chinese males and 14 females varying in age from 17 to 53 yr. and 5 Anglo-Saxon males and 21 females varying in age from 15 to 60 yr. were determined with the Benedict field metabolism apparatus. All the subjects were living at an altitude of approximately 1,800 ft. The nutritional status was in general normal. The following average percentage deviations from prediction standards were obtained: Chinese males, +1.9 from the Harris-Benedict and -2.4 from the Aub and Du Bois; Chinese females, -3.7 and -3.3; Anglo-Saxon males, -0.3 and -5.3; and Anglo-Saxon females, +1.8 from the Harris-Benedict and -3.1 from the Aub and Du Bois. These results indicate that the Chinese of Szechwan possess a basal metabolic rate differing very little from that of westerners living in the same region.

The basal metabolism of the Miao race of Kweichow, L. G. KILBORN and F. G. BENEDICT (*Chin. Jour. Physiol.*, 11 (1937), No. 1, pp. 127-134).—The basal metabolic rates of 23 male Hwa Miao and 1 male Chwan Miao living at an altitude of about 7,000 ft. were determined with a Benedict field metabolism apparatus. The average age of the subjects was 32 yr. The average deviation from the Harris-Benedict standard was +15.8 percent and from the Aub and Du Bois +9.2 percent, with an average pulse rate of 55 per minute. It is concluded that the Miao race is characterized by a relatively high basal metabolic rate.

The state of nutrition of school children in south India, I. W. R. AYERBOYD and K. RAJAGOPAL (*Indian Jour. Med. Res.*, 24 (1936), No. 2, pp. 419-437, pl. 1, figs. 4).—In this investigation approximately 2,000 school children, aged from 6 to 17 yr. and living in three south Indian towns, were weighed, measured, and examined for symptoms of xerophthalmia, "angular stomatitis", and phrynoderma. The A. C. H. index (A=arm, C=chest, H=hip) of nutrition, as described by Franzen (*E. S. R.*, 71, p. 573) and Palmer was applied to 1,145 children of the group aged from 6 to 12 yr. The height and weight averages for boys aged from 6 to 15 yr. were compared graphically with those of other groups of Indian, Ceylonese, British, and American boys.

The diets of the children were composed largely of milled rice with small quantities of vegetables. Malnutrition due to diet deficiencies was very prevalent, symptoms of food deficiency diseases being found in 14 percent of the cases, while 6.4 percent showed phrynoderma, 9.2 angular stomatitis, and 3.8 Bitot's spots. A group of 25.7 percent was selected by the A. C. H. index as compared with a 10-percent selection for American children. It is suggested that the index needs adjustment for application to Indian children. The Indian boys of a given height weighed very much less than British or American boys of the same height.

The copper content of some human and animal tissues, P. F. HAHN and E. FAIRMAN (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 161-165).—The chromo-

tropic acid method described by Ansbacher et al. (E. S. R., 66, p. 505) was followed in determining the copper content of fresh tissues from 14 humans and from 4 normal and 9 anemic dogs.

The amount of copper present in the human liver varied from 3.3 mg in a patient with myeloid leucemia to 15 mg per kilogram of fresh tissue in a 7-year-old child with Mediterranean anemia. The splenic copper content of 4 subjects varied from 1 to 2.9 mg per kilogram of fresh tissue. The copper content of the fetal and infant livers varied from 3.4 mg in a 9-week infant with pneumonia to 73 mg in a 5-mo. fetus born prematurely.

The copper content of the livers of anemic dogs receiving iron administration varied from 15 to 61 mg, and the spleen content varied from 5 to 26 mg per kilogram of fresh tissue. It was noted that as the iron store in the spleen was depleted the copper store increased. The same tendency, but to a less degree, was noted in the anemic dog liver.

Studies on magnesium deficiency in animals.—VII, The effects of magnesium deprivation, with a superimposed calcium deficiency, on the animal body, as revealed by symptomatology and blood changes, H. G. DAY, H. D. KATSE, and E. V. MCCOLLUM (*Jour. Biol. Chem.*, 112 (1935), No. 1, pp. 337-359, figs. 2).—In this continuation of the series (E. S. R., 72, p. 876), a deficiency of calcium in the diet of young dogs was superimposed upon a magnesium deficiency by altering the salt composition of the diet to contain approximately 0.002 percent of calcium and 0.0002 percent of magnesium as compared with approximately 0.61 percent of calcium and 0.054 percent of magnesium in the control diet.

The symptomatology and blood chemical changes appeared to resemble those of low calcium rather than low magnesium alone and are summarized as follows:

"The dietary deficiency is manifested by edema, gastrointestinal disturbance with alternate constipation and diarrhea, osteoporosis with consequent deformation of the bones, in a few cases of hyperirritability of the nervous system, which led to fatal convulsions, but in the majority of cases by a marked inertness, and anorexia which usually led to death by consequent inanition. The blood chemical data, obtained by weekly analysis throughout the survival period, reveal an immediate decrease in serum magnesium quantitatively similar to that which induces tetany in magnesium deprivation. Serum calcium likewise diminished to levels usually indicative of tetany. Alkali reserve and pH diminished, blood chlorides mounted as the erythrocyte volume fell, fibrinogen increased, terminally inorganic phosphorus decreased, and nonprotein nitrogen rose. Significant changes did not appear in serum sodium and potassium, plasma total lipids, fatty acids, total cholesterol, cholesterol esters, lipid phosphorus, serum bile pigment, and plasma albumin and globulin."

The effect of mono-, di-, and tricalcium phosphates on reproductive success in rats, W. M. COX, JR., and M. IMBODEN (*Jour. Nutr.*, 12 (1936), No. 5, pp. 509-514, fig. 1).—In continuation of a previous study (E. S. R., 76, p. 129) and with the same basal diet and technic, similar experiments were conducted during 11 reproductive cycles to determine the effect of primary, secondary, and tertiary calcium phosphates fed at a high calcium level. With the level of calcium intake at 2.45 percent of the diet, the range of calcium:phosphorus ratios which insured optimum reproductive performances was from 1.2 to 1.7 approximately. The tertiary phosphates with a calcium:phosphorus ratio of 1.63 gave a final success grade of 79.5 with 40 complete gestations and none incomplete, 324 living young of which 216 were available to raise, 37 complete

lactations, 76.4 percent of the available young raised, and an average weight at the end of the weaning period of 46.37 g. The secondary phosphate with a calcium:phosphorus ratio of 1.15 gave a final success grade of 73.6 with 46 complete gestations and 1 incomplete, 378 living young and 251 available to raise, 27 complete lactations, 46.6 percent of the available young raised, and an average weight of 40.01 g at 21 days of age. The primary phosphates proved inadequate for reproductive processes, giving a final success grade of 6. The mother rats on the secondary and tertiary phosphates showed no gross signs of excessive mineral intake on the high calcium ration and in the absence of vitamin D.

A note on the identity of the indophenol-reducing substances in brain tissue, F. G. Young (Biochem. Jour., 50 (1956), No. 10, pp. 1885-1885).—Chemical evidence is presented to show that the existence of an indophenol-reducing factor other than ascorbic acid in brain tissue has not been conclusively demonstrated. A crude extract was obtained from ox brain by alcoholic extraction which contained approximately 1 milligram equivalent of an indophenol-reducing factor per cubic centimeter. The extract at pH 10 was inactivated by aeration, readjusted to the original pH value, and pure ascorbic acid was added in an amount equivalent to the indophenol-reducing factor removed by aeration. The properties of this "reconstituted crude extract" were compared with those of the original crude extract. The ascorbic acid and indophenol-reducing factor present were estimated by the reduction of 2,6-dichlorophenol-indophenol, following the technic of Birch et al. (E. S. R., 70, p. 741).

Since the properties of the reconstituted crude brain extract containing pure ascorbic acid resembled those of the crude brain extract containing the indophenol-reducing factor, "there is, therefore, no reason to believe that the indophenol-reducing substance in crude brain extracts is other than ascorbic acid."

Recent trends in vitamin research, R. A. DUTCHER (Jour. Home Econ., 28 (1956), No. 3, pp. 621-630).—The author discusses representative types of research work and reviews particularly the types of investigations carried on at Pennsylvania State College. "It would appear . . . that the predominating trends in vitamin research at present (as in the recent past) are in the direction of the isolation of vitamins and the determination of configuration followed by laboratory synthesis; the improvement and standardization of assay technics and of vitamin unitage; the reestimation of vitamin content of foods, vitamin stability during food processing, and so on, using the newer technics; and further elucidation of the vital physiological functions of vitamins in the living organism."

The effect of processing on vitamins in fruits and vegetables: A review, C. R. FELLERS (Massachusetts Sta. Bul. 338 (1956), pp. 23).—This literature review covers the effects of storage, freezing, drying, and thermal treatments on the various vitamins as present in fruits and vegetables. Less than a page each is given to vitamins D and E, a little over one to vitamin G (B₂), two pages to vitamin B (B₁), about three pages to vitamin A, and eight pages to vitamin C, the distribution of space reflecting the extent of work on vitamin C since the development of a rapid chemical method for its determination. General conclusions are given concerning the stability of the various vitamins to the factors studied, and a list of 235 references is appended.

The accuracy of vitamin A determinations.—The starting-point of the test period, K. H. COWARD (Biochem. Jour., 50 (1956), No. 11, pp. 2009-2011).—In continuation of previous studies (E. S. R., 68, p. 595), the author calculated from the formula $\lambda = \sigma/\text{slope of curve of response}$, the degree of accuracy of the test obtained during each of the 5 weeks of dosing the experimental rat.

The calculation is based on data obtained from 960 male and 1,110 female rats. All of these had lost weight before receiving the vitamin A supplement, and many continued to lose weight for a short time before recovery began.

The greatest accuracy was obtained by counting the test period from the first day of dosing, since it was found that the slope of the curve of response for each week's increase in weight became slightly less in successive weeks, while σ remained constant.

The utilization by the rat of vitamin A and carotene administered in different media, K. H. COWARD (*Biochem. Jour.*, 30 (1936), No. 10, pp. 1878-1882).—A comparison was made of the variation in the response of large numbers of rats to the vitamin A contained in cod-liver oil, the carotene in plant tissue, the vitamin A and carotene in butter, and the vitamin A of margarines containing a vitamin concentrate. Approximately 2,100 rats were maintained on a vitamin A-free diet supplemented by doses of the test material or the vitamin A standard. The response of rats to a dose of vitamin A given daily for 5 weeks after they had ceased to grow on the A-deficient diet was estimated from the calculated standard deviation of a single determination (E. S. R., 68, p. 565).

No significant difference in response was noted, and it is concluded that there is no difference in the ability of animals to utilize vitamin A or carotene administered in different media. "The causes of the difference in effectiveness of carotene dissolved in different oils must be sought elsewhere."

Studies on vitamin A deficiency.—I, Xerophthalmia and trigeminal nerve degeneration, M. V. RADHAKRISHNA RAO (*Indian Jour. Med. Res.*, 24 (1936), No. 2, pp. 439-457, pls. 8).—The relationship between xerophthalmia and lesions occurring in the sensory nerve of the eye was investigated in young rabbits, rats, and fowls on vitamin A-deficient, stock, and control diets; on groups of rats and rabbits maintained on vitamin B₁-deficient diets; and on animals receiving carotene supplements to the vitamin A-deficient diets. The animals were killed at various periods before and after the development of xerophthalmia, and the eye and its adnexa, Gasserian ganglia, liver, and other tissues were studied macroscopically and microscopically. The trigeminal nerves with their branches, optic nerves, and some of the peripheral nerves were also examined.

The rabbits proved to be the most satisfactory experimental animals, due to the regularity with which they developed xerophthalmia. The degenerative changes present in the nerve cells and fibers did not appear to be specific for vitamin A deficiency, since similar changes were noted to a less degree in the animals maintained on the vitamin B₁-deficient diets. The following observations are made:

"Xerophthalmia and myelin degeneration in the afferent nerves of the eye were often present in animals deprived of vitamin A and carotene. Varying degrees of myelin degeneration in the sensory nerve . . . supplying the conjunctiva and cornea were present before the appearance of any lesions, macroscopic or microscopic, in the latter. When xerophthalmia was present there was no exact parallelism between the intensity of the changes present in the corresponding sensory nerve and in the cells of the Gasserian ganglion and the intensity of the eye lesions. Animals in which the eye lesions on either side varied markedly showed about the same degree of degeneration in both the corresponding trigeminal nerves. Complete recovery of the lesions and the corresponding sensory nerves did not occur in animals in which the corneal lesions were healed by the addition of carotene to the diet. There is no evidence to suggest that xerophthalmia is secondary to a loss of the neurotrophic control of the ophthalmic division of the trigeminal nerve."

The use of colloidal adsorbents with vitamin B.—A preliminary study, D. STEIN and E. H. KOTIN (*Clin. Med. and Surg.*, 44 (1937), No. 3, pp. 115-117).—Kao-Lactos B, which consisted of approximately 50 percent colloidal kaolin and 50 percent lactose, with 125 units of vitamin B₁ and 25 units of vitamin B₂ per ounce, was fed to 12 patients aged from 10 to 60 yr. showing clinical symptoms of avitaminosis and secondary anemia, together with diseased conditions of the gastrointestinal system. The synergistic effect of the vitamin B₁ to the action of the colloidal kaolin was studied by noting the general progress made by the patients during the 3 mo. of treatment and the changes in hemoglobin percentage, red blood cell count, and sedimentation rate.

A general improvement and feeling of well-being were noted, with increase in weight, red blood cells, and hemoglobin, and a lowering of the sedimentation rate. One case of carcinoma of the colon showed some symptomatic improvement, although the organic lesion progressed. Cases of chronic cholecystitis and tuberculous enteritis were temporarily relieved, and excellent results were obtained in functional cases of duodenitis and ulcerative colitis. In most cases gaseous eructations and constipation were relieved.

The influence of the length of the test period on the accuracy obtainable in a vitamin B₁ test. K. H. COWARD (*Biochem. Jour.*, 30 (1936), No. 11, pp. 2012-2015).—Following the technic previously described (E. S. R., 70, p. 876) of testing for vitamin A by the increase in weight method, the author determined the average variance in response of male and female rats to doses of vitamin B₁ in tests lasting 1, 2, and 3 weeks, and measured the slope of the curves of response relating increase in weight to the vitamin B₁ dose. The formula $\lambda = \sigma / \text{slope of curve of response}$ was used to determine the degree of accuracy obtained in the test.

The curve of response of bucks was only very slightly steeper than for does, showing that equal numbers of each sex in each group are not necessary. With 10 pairs of animals the probable error of a determination of vitamin B₁ was approximately 18, 12.5, and 10 percent, respectively, for the first, second, and third weeks. Thus, the accuracy was only very slightly increased by extending the test period from 2 to 3 weeks.

Experiments upon the extraction and stability of vitamin B (B₁) and of lactoflavin. B. BISSEY and H. C. SHERMAN (*Jour. Biol. Chem.*, 112 (1935), No. 1, pp. 415-420, fig. 1).—The extraction of vitamin B₁ and flavine from skim milk powder is described, and a series of fractional extraction experiments in which the extraction was carried through first with absolute alcohol and later with 80 percent alcohol are discussed. Feeding tests on rats were made with the preparations, following the methods (E. S. R., 66, p. 410) of Chase and Sherman for determining vitamin B₁ and of Bourquin and Sherman for flavine.

The vitamin B₁ values were found to be well conserved by this method of extraction and the vitamin G or flavine values to a less extent. Practically all of the vitamin B₁ was extracted from the milk by 80 percent alcohol and practically none of it by absolute alcohol. The flavine was not measurably extracted by absolute alcohol and only a portion of it by 80 percent alcohol. The symptoms of nutritional deficiency in the experimental animals served as a means of identifying the two factors.

Vitamin B in lamb tissues and organs. M. KILGORE (*South Dakota Sta. Bul.* 306 (1936), pp. 45).—This is the complete report of an investigation noted previously from progress reports (E. S. R., 75, p. 728). The term vitamin B as used in the studies reported includes vitamin B₁ as determined by the method of Chase and Sherman and B₂ (G) as determined by the method of Bourquin and Sherman (E. S. R., 66, p. 410). Attention is called to the report

of Bisbey and Sherman noted above, indicating that the Bourquin-Sherman method is a measure of the flavine component of the vitamin B complex. The lambs used were well-finished, with carcasses graded as choice. The B₁ determinations were made on the fresh material and the flavine values on canned material autoclaved at 15 lb. pressure for 1 hr.

The estimated values for vitamin B₁ are given as meat 2+, liver 2+, kidney 3+, heart 3, tongue 1—, brain 2, and pancreas 2 Sherman units per gram of fresh material. Corresponding values for B₂ (flavine) are meat 1.3, liver 6.6, kidney 6.6, heart 10, tongue 2, brain 1.6, pancreas 3.3, and thymus 10 units per gram of canned material. These values indicate that vitamin B₁ is fairly evenly distributed in lamb tissues and organs, while vitamin B₂ (flavine) varies widely.

Growth-promoting activity of lactoflavin administered orally and parenterally. P. GRÖNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 207-209).—The physiologic growth-promoting actions of free lactoflavine and of pure (synthetic) lactoflavine-5-phosphoric acid were compared by the administration to rats of graded doses of each form, orally and parenterally, following the method of feeding experiments previously described (E. S. R., 75, p. 282). The casein AB Glaxo and rice starch in the basal diet were replaced by extracted casein and cornstarch, respectively.

The results indicate that the growth-promoting effect of lactoflavine or of lactoflavine-5-phosphoric acid is independent of the way it is administered and that the two materials are biologically similar, since the average weekly weight gain was approximately 5 g when from 3.2γ to 15γ of either material was administered orally or parenterally each day. The rat day dose for both is about from 7γ to 10γ. "It can therefore safely be assumed that the phosphorylation of lactoflavine is not only an intestinal but also a general cellular reaction."

Lactoflavin in the treatment of canine blacktongue. W. H. SEEBELL, D. J. HUNT, and R. H. ONSORR (*Pub. Health Rpts. [U. S.]*, 52 (1937), No. 2, pp. 235-239).—Five dogs were placed on the basic blacktongue-producing diet No. 123 of the following composition: Corn meal 400 g, cowpeas 50, purified casein 60, sucrose 32, cottonseed oil 30, cod-liver oil 15, sodium chloride 10, and calcium carbonate 3 g. The dogs showed well-developed attacks of the blacktongue within from 36 to 73 days. The administration by mouth of from 6 to 10 mg of riboflavin (L. F. No. 356) to four animals and 38 mg to the fifth one failed to relieve the symptoms, and death ensued in from 1 to 30 days after beginning the treatment. These results are thought to add "further evidence to the view that riboflavin is distinct from the blacktongue-preventive factor."

The treatment of blacktongue with a preparation containing the "filtrate factor", and evidence of riboflavin deficiency in dogs. W. H. SEEBELL, R. H. ONSORR, and D. J. HUNT (*Pub. Health Rpts. [U. S.]*, 52 (1937), No. 15, pp. 427-433).—Five dogs were placed on the basic blacktongue-producing diet No. 123, referred to above. When symptoms of blacktongue developed, rice bran filtrate K-37-A was given until they subsided and again upon recurrence.

Typical signs of acute blacktongue developed in the five animals in 131, 55, 13, 83, and 55 days, respectively, from the beginning of the experiment. One animal died in an attack of blacktongue without treatment, while three died in 115, 54, and 117 days, respectively, from the beginning of treatment with the filtrate without any signs of blacktongue, indicating the presence of the blacktongue-preventive factor in the filtrate. The remaining dog, while in a semicomatose condition 182 days after the beginning of the treatment identi-

cal with that which just preceded the deaths of the other three dogs, was given 8 mg intramuscularly of riboflavin (L. F. 356) and within 12 hr. had returned to normal. The blacktongue-producing diet No. 123 is thought to be deficient in riboflavin as well as in the blacktongue-preventive factor, and the deficiency in riboflavin the cause of the collapse and sudden death of the animals in the absence of signs of blacktongue.

Stomatitis due to vitamin B₂ deficiency, W. R. AYKROYD and B. G. KRISHNAN (*Indian Jour. Med. Res.*, 24 (1936), No. 2, pp. 411-417, pl. 1).—Stomatitis, with erosions of the lips, mucous membrane of the tongue, and angles of the mouth, was observed in 16 boys and 25 girls, representing approximately 60 percent of the school children in two residential hostels. The diets were composed largely of milled parboiled rice and were deficient in almost all food factors. The general state of nutrition of the children was very poor. Four boys were given 1 oz. daily of dried brewers' yeast and the sore mouths were healed in from 1 to 4 weeks. The administration of 14 g of cod-liver oil daily for 3 weeks to 9 boys did not cure the condition until 1 oz. daily of the dried brewers' yeast had been given for from 4 to 7 weeks. The addition of 42 g of dried skim milk daily to the diet of the girls brought about a cure in all cases within from 3 to 4 weeks. The general condition of the children was noticeably improved following the administration of yeast and skim milk. It is assumed that the stomatitis was due to the deficiency of one or more of the factors in the vitamin B₂ complex.

Bacterial toxins and vitamin C in relation to tooth structure, W. F. SWANSON, A. SIGAL, and C. G. KING (*Jour. Amer. Dental Assoc.*, 23 (1936), No. 11, pp. 2089-2096, figs. 10).—Observations on the teeth of guinea pigs are recorded, with microphotographs, indicating "(1) that bacterial toxins may have an important role in causing injury to developing tooth structures without involving an actual infection of the tooth, and (2) that a high vitamin C intake or nutritional level is important in relation to the natural protection against such injury."

After from 10 to 15 days on a modified Sherman vitamin C-free diet, groups of guinea pigs were given varied doses of pure vitamin C daily, with and without subcutaneous injections of a bacterial toxin (diphtheria). Guinea pigs in the prescurbic stage were found to be subject to marked injury to tooth structure from the bacterial toxin. The teeth of the animals on a high vitamin C intake and receiving toxin injections were only occasionally irregular.

Storage of vitamin C by normal adults following a period of low intake, P. H. O'HARA and H. M. HAUCK (*Jour. Nutr.*, 12 (1936), No. 4, pp. 413-427, fig. 1).—The subjects were four normal adult women maintained on an otherwise adequate basal diet containing 5 mg of vitamin C daily. During a 4- to 5-day preliminary period orange juice containing from 88 to 100 mg of ascorbic acid was given to insure a condition of vitamin C saturation. For from 29 to 30 days the basal diet alone was ingested, and then 200 mg of ascorbic acid in the form of orange juice were added until the subjects were again saturated, as shown by a constant urinary output of vitamin C. Capillary resistance tests were made weekly by the G  thlin method (*E. S. R.*, 72, p. 422) and daily by means of the resistometer devised by Dalldorf (*E. S. R.*, 73, p. 731). The Bessey and King method of titration with indophenol (*E. S. R.*, 71, p. 137) was essentially followed in determining the vitamin C content of foods and urine specimens before and during the experimental period. All subjects were examined by a physician for symptoms of latent scurvy at the end of the 30-day period on the low vitamin C diet, and, with the exception of slight gingival bleeding in one subject, no clinical symptoms were found.

The ascorbic acid excretion fell below 0.02 mg per cubic centimeter per 24 hr. at about the second day of the low vitamin C intake and did not return to that level until from 5 to 9 days after the 200 mg of ascorbic acid supplement had been administered, at which time the total urinary excretion of vitamin C ranged from 18 to 36 mg. Following the ingestion of the ascorbic acid supplement the concentration of vitamin C in the urine rose to 0.04 mg per cubic centimeter. From 2,200 to 2,540 mg of vitamin C were required to restore the tissues to saturation following the period of low intake. If, as is suggested, the basic tissue reserve is represented by the difference between intake and excretion up to the point of saturation following prolonged deprivation of vitamin C, the maximum tissue reserve would appear to be about 2,500 to 3,000 μ g.

During a 14- to 17-week test period marked variations in capillary resistance were noted, both in the same individual from time to time and in different individuals, and no correlation could be demonstrated either between the results obtained by the two methods or between the data on capillary resistance and the urinary excretion of vitamin C. It was concluded that capillary resistance did not give an adequate indication of the vitamin C metabolism.

Effect of home canning and storage on ascorbic acid content of tomatoes. E. P. DANIEL and M. B. RUTHERFORD (*Food Res.*, 1 (1936), No. 4, pp. 341-347).—In this contribution from the U. S. D. A. Bureau of Home Economics, ripe tomatoes of the Stone variety obtained from the same patch on 5 consecutive days were sampled, and the whole fruit and juice were canned in both glass jars and tin cans by the water bath method. Samples were tested after 24 hours' storage, and half of the remaining glass jars were wrapped in black photographic paper to exclude the light before being stored for 6 mo. The Bessey and King modification of Tillmans' titrimetric method (E. S. R., 71, p. 137) was followed in the determination of ascorbic acid, six titrations being made for each sample.

The fresh tomato contained an average of 0.2 mg of ascorbic acid per gram of extracted juice, with considerable variation among the different lots of fruit. The loss of ascorbic acid from the whole tomato, due to the canning process, was 21 percent in both unwrapped and wrapped jars, with 10 and 23 percent additional loss, respectively, during 6 months' storage. The tomato juice in the unwrapped glass jars lost 21 percent during the canning process and 24 percent during storage, while in the wrapped jars the values were, respectively, 21 and 34 percent. Whole tomatoes in tin cans lost 12 percent during canning and 13 percent during storage. The values for tomato juice in tin cans were, respectively, 11 and 10 percent. It appears that from one-fourth to one-half of the ascorbic acid content of home-canned tomatoes stored at ordinary room temperature may be lost before the fruit is consumed, with the greatest loss occurring in the whole fruit and juice in glass containers with the light excluded and the least loss in tin containers.

HOME MANAGEMENT AND EQUIPMENT

A study of price differences in retail grocery stores in New York State. L. DOMAN ([*New York*] *Cornell Sta. Bul.* 665 (1937), pp. 52).—This study was made "to obtain information relative to the money savings possible for household buyers who can take advantage of the differences in prices commonly found among retail grocery stores. Three types of price differences were studied: (1) Differences between sale prices and regular prices of identical articles in the same store. (2) Differences between prices of identical articles on the same day in stores of the same shopping district, and (3) differences

between prices on different quantities of identical products in the same store." Regular prices and sales prices (6,358 sale offers during February-May 1931) of canned and packaged goods and bulk granulated sugar and bulk rice sold by grade were collected from 141 chain, 32 cooperative chain, and 77 independent stores in 59 localities of the State with a population of from less than 1,000 to approximately 560,000 people.

Analysis was made of the reductions on sale offers in the case of unit and multiple-unit and combination and premium offers, the offers of different brands of goods and in different commodity groups, commodities of different prices, etc. Comparisons were made of prices at high- and low-price stores and of prices on the basis of quantity, size of containers, etc. The significance of differences of prices to household buyers is discussed.

Seventy-three percent of the unit and multiple-unit sale offers were lower than the regular price quotations on the same articles, 25 percent at regular prices, and 1 percent at higher than regular prices. The percentages of reduction ranged from 1 to 50, averaging 14.4, in chain stores; from 1 to 50, averaging 14.8, in cooperative chain stores; and from 1 to 52, averaging 15.6, in independent stores. The reductions on combined unit and multiple-unit sale offers from all stores averaged 5 ct. on each offer and 2 ct. on each unit included. "There were no significant differences in price reductions on the goods of different brands", the average reduction being 14.8 percent. "The average percentage price reductions on sale offers of specific classes of goods did not vary greatly from the average on all offers combined." "In 17 of the 33 districts studied, the differences between high and low prices on all 20 articles priced in the districts—each expressed as a percentage of the high price of the district—averaged from 11 to 15 percent."

Home conveniences on Tennessee farms with regional comparisons, C. E. ALLEED and W. E. HENDRIX (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 30* (1937), pp. [1]+III+41, figs. 21).—In the nine representative Tennessee counties studied, 96.6 percent of all farm dwellings are heated by fireplaces and stoves. Electric lights are used in 5.5 percent. Wells furnish water for 53 percent, springs and cisterns each for about one-fourth, and streams for 1.3 percent, with 10 percent of the farms having running water piped into dwellings, and 90 percent carrying water for an average distance of 209 ft. Either improved outdoor toilets or indoor chemical or flush toilets are used in 17.8 percent of the farm homes, 52.3 percent use unimproved outdoor privies, and 29.4 percent lack toilet facilities. Bathtubs are found in 2.7 percent of all farm dwellings, showers in 0.9 percent, and lavatories in 2.1 percent. Of dwellings occupied by white owners, 10 percent have kitchen sinks with drains, compared with 2.4 percent for white tenants, 0.6 percent for Negro owners, and 0.3 percent for Negro tenants. More than one in five (21 percent) farm families have refrigerators in their home, and the proportion in Obion County is 60 percent. Few farm families have improved laundry facilities. Wood or coal stoves are used in 93.6 percent of all farm homes for cooking. Eighteen percent of the farm families in the State had telephones in 1930 and 4.8 percent had radios. Lawns have been established by 64 percent of the farm families surveyed, and plantings of shrubbery have been made by 56 percent.

Census data on electric lights, running water in dwellings, and radios show that the percentage of farm people in the State as a whole using these facilities has more than doubled since 1920. The percentage of farms reporting telephones, however, decreased from 22.5 percent in 1920 to 18 percent in 1930.

"A comparison of Tennessee with other States shows that Tennessee ranks high among Southeastern States in modern improvements for the homes. In most items, however, other regions of the United States are above the Southeastern States."

Selection and use of the electric iron, P. B. POTTER and F. H. BASS (*Virginia Sta. Bul. 307 (1937), pp. 30, figs. 12*).—This publication includes a preliminary discussion of the ironing process, with data on the optimum moisture content and temperatures for ironing linen, cotton, and rayon fabrics. The results are then presented and discussed of performance tests on 21 electric irons of well-known makes and models. The irons are listed by code number, with data on wattage rating, weight, area of ironing surface, and watts and weights per square inch of surface. The series of tests reported include block or no load, operating, scorch, and life tests, with checks on thermostat action and repeat block tests.

To aid the housewife in the interpretation of the data for the selection of an electric iron, certain features which should be considered are discussed in some detail. These include weight, wattage, thermostat, cords, and miscellaneous features. Finally, a list of suggested standard specifications for electric irons in terms of safety, size, durability, performance, and guarantee is presented, with the recommendation that all irons operated by electricity and designed for household use should meet these tests and specifications and "upon so doing should be marked with a distinctive emblem by the manufacturer as an indication and guarantee of first grade quality and performance."

MISCELLANEOUS

Forty-seventh Annual Report of the Storrs Agricultural Experiment Stations, Storrs, Connecticut, for the year ending June 30 1935, W. L. SLATE ET AL. (*[Connecticut] Storrs Sta. Rpt. 1935, pp. [440], figs. 55*).—This includes reprints of Bulletins 207-212, previously noted, and of Bulletin 213, abstracted on page 552 of this issue.

Report of the director [of the Storrs Station], 1936, W. L. SLATE (*[Connecticut] Storrs Sta. Bul. 214 (1937), pp. 31*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Biennial Report of the Rice Experiment Station, Crowley, Louisiana, 1935-1936, J. M. JENKINS ET AL. (*Louisiana Sta., Rice Sta. Bien. Rpt. 1935-36, pp. 19*).—The experimental work not otherwise referred to is for the most part noted elsewhere in this issue.

Fifty-seventh Annual Report of the New Jersey State Agricultural Experiment Station and the Forty-ninth Annual Report of the New Jersey Agricultural College Experiment Station for the year ending June 30, 1936, J. G. LIPMAN (*New Jersey Sta. Rpt. 1936, pp. XXIII+145*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Findings in farm science from Wisconsin's proving ground: Annual report of the director [Wisconsin Station, 1936], compiled by N. CLARK and N. HOVELAND (*Wisconsin Sta. Bul. 438 (1937), pp. [2]+168, figs. 37*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

NOTES

Purdue University and Indiana Station.—Dean and Director J. H. Skinner has returned from a 7 months' leave of absence. Dr. J. L. Roberts became soil microbiologist July 1.

Massachusetts Station.—Dr. Carl Olson, Jr., assistant professor of pathology and bacteriology in the New York State Veterinary College, has been appointed research professor in veterinary science, primarily for studies of poultry problems.

Montana College and Station.—Dr. A. L. Strand has been appointed president effective August 1. He has been succeeded as head of the department of entomology and State entomologist by Dr. H. B. Mills, previously assistant State entomologist.

New Hampshire Station.—Fire on July 12 destroyed the agricultural engineering building, originally the dairy barn. It will be replaced by a brick structure.

North Dakota Station.—Dr. H. C. Hanson, chairman of the department of botany and plant pathology, has been appointed acting director, effective August 13, Dr. H. L. Walster continuing as dean of the division of agriculture.

Rhode Island Station.—Beginning June 1, the station staff became eligible under the State Retirement System, a contributory insurance plan with the State paying a portion of the premium. Workers at the station previous to July 1, 1936, were given credit for this service. Retirement is optional at the age of 60 and compulsory at 70.

Dr. Irene H. Stuckey has been appointed assistant plant physiologist, beginning July 1.

Utah Station.—Dr. Lowry Nelson resigned as director on August 31 to become professor of rural sociology in the University of Minnesota.

Virginia Polytechnic Institute.—A tract of 2,500 acres in Giles County has been acquired for the use of the biological department. This land is located 18 miles from the college, adjacent to the Jefferson National Forest at an elevation of from 2,000 to 4,000 ft., and provides a wide variety of flora and fauna. It is planned so to manage the area as to restore primitive conditions, though some demonstrations in wildlife and forestry management will be undertaken. The tract is expected to be of special value for advanced students in wildlife conservation, forestry, botany, zoology, plant pathology, and entomology.

Fourth International Grassland Congress.—This Congress was held at various points in Great Britain from July 8 to 23, 1937, under the presidency of Director R. G. Stapledon of the Welsh Plant Breeding Station. The attendance numbered about 450, representing 37 countries, the largest delegation from abroad being that of the United States. In addition to a large number of papers, tours over much of England, Scotland, and Wales were a special feature of the program.

Invitations were received to hold the Fifth Congress in 1940 in the Netherlands and the Sixth Congress in 1943 in Hungary. The invitation for 1940 was accepted, and its proponent, Dr. J. Huizinga, elected president. A volume of abstracts of all papers read at the Congress is already available, and it is expected that the full report of the proceedings will be ready this fall.

EXPERIMENT STATION RECORD

VOL. 77

NOVEMBER 1937

No. 5

ADDITIONAL CHANGES IN EXPERIMENT STATION LEADERSHIP

The calendar year 1937 seems likely to be associated in experiment station annals with an unusual number of changes in the leadership of these institutions. Reference has already been made in the *Record* to the death of Director C. P. Blackwell of Oklahoma, the retirement of Directors F. B. Linfield of Montana and C. G. Williams of Ohio, the transfer to full-time service as dean of the division of agriculture of Director H. L. Walster in North Dakota, the resignation of Director Lowry Nelson in Utah, and the return to experiment station work of former Director P. S. Burgess in Arizona. In addition, supervision of the experiment station and extension service in the Alaska College has now been combined under Director L. T. Oldroyd of the extension service, with the former station director, G. W. Gasser, continuing as dean of men and professor of agriculture. In Maryland Director H. J. Patterson retired on October 1 under the new university retirement act, and announcement has been made of the prospective retirement early in 1938 of Director U. P. Hedrick of the New York State Station. Most recent of all, at the time of writing, is the resignation of Director R. Y. Winters of North Carolina as of October 15, 1937, to accept an appointment as a principal experiment station administrator in the Office of Experiment Stations.

Thus there are disappearing from the station ranks many leaders of long experience and unique service. Among these, special mention should be made of Director Patterson, whose association with the Maryland Station covers virtually its entire history. A graduate of the Pennsylvania State College in 1886 and with 2 years' service as assistant chemist in that institution, he was appointed chemist of the Maryland Station soon after its organization in 1888. About 10 years later he began his service of nearly 40 years as director, also serving as president of the college from 1913 to 1917 and since 1925 as dean of agriculture. Thus he has been intimately identified with the growth and development of the institution for nearly half a

century. When he was appointed director, the station staff numbered 13 and the annual income was under \$17,000. For the past year there were over 60 staff members and an income in excess of \$200,000. Supported for many years entirely from Federal funds, the station now receives about \$100,000 annually from State sources. This evolution is a tangible recognition of the interest which he did much to arouse and reflects the confidence which he has consistently inspired and retained. He will be greatly missed by the institution in whose upbuilding he has played so prominent a part. In his stead there has been appointed as acting director of the station J. E. Metzger, assistant director and head of the department of agronomy.

Director Hedrick is also bringing to a close a long period of conspicuous station activity. A recipient from the Michigan College of the B. S. degree in 1893 and the M. S. degree in 1895, he engaged in horticultural teaching and investigation in the agricultural colleges and experiment stations of Michigan, Oregon, and Utah until he was appointed head of the department of horticulture in the New York State Station in 1905. Sixteen years later he was named vice director, and in 1928 director. As an investigator he became widely known as a developer of numerous outstanding varieties of fruits and as author of a series of monographs of the hardy fruits and of *A History of Agriculture in the State of New York*, published in 1933. As director, Dr. Hedrick has striven especially for three objectives—the enlargement of the station's physical plant, the beautification of its grounds, and, without sacrifice of research ideals and programs, the development of closer relations with the farmers of the State through the simplification and popular interpretation of its published material and the wide dissemination of its results. In all of these respects, as well as in others, distinct progress has been made under his leadership. An already strong station has been further strengthened.

Director Winters severs an association with the North Carolina Station of nearly 26 years, of which about half have been devoted to constructive administration. Born in South Carolina in 1886, he received from Clemson College the B. S. degree in 1906, and the honorary D. Sc. degree in 1937, the M. S. degree from the University of Florida in 1909, and the Ph. D. degree from Cornell University in 1911. After some years of botanical work in the University of Florida and Cornell University, he was appointed agronomist and plant breeder in North Carolina in 1912, and became director in 1925. In addition to building up the station itself in various ways, he has been active in many regional cooperative undertakings in the Southeast and is unusually familiar with its agricultural problems. In his new duties with the Office of Experiment Stations, it is expected to

make wide use of his distinctive research and administrative experience and outlook in the development of projects and programs in this region, which receives a large percentage of funds under the Bankhead-Jones Act and presents an especially attractive opportunity.

SIXTH GENERAL INDEX TO EXPERIMENT STATION RECORD

The recent publication of the sixth general index to *Experiment Station Record* makes available in convenient form subject-matter references to all material printed in these columns before July 1934. Ten volumes are again included, volumes 61-70, covering the period 1929-34.

The new general index follows closely the lines of its predecessors, preserving the continuity of policy and treatment. The total number of pages is 752, an increase of over 10 percent over the previous index. The subject index entries approximate 60,000, and under many of them, of course, a number of references are made. This expansion reflects the ever-increasing bulk of the literature covered.

Largely because of the high cost of publication of an index of this type, the edition is much smaller than for the monthly issues of the *Record*, precluding a distribution to the regular mailing list. The needs of libraries are being met, however, and it is thought that the supply will permit a reasonably complete institutional distribution. Individuals and others not eligible for inclusion in the free distribution should find no difficulty in purchasing the index from the Superintendent of Documents, Government Printing Office, Washington, D. C. The price set by that official is 75 ct. per copy.

Inquiry is frequently made as to the earlier general indexes. The second of these, covering volumes 13-25, has been completely exhausted for some time, but there is still a small reserve stock for the remaining issues. The index for volumes 1-12 may be purchased from the Superintendent of Documents for 50 ct., and the indexes for volumes 26-40, 41-50, and 51-60 for 75 ct., \$1.25, and 60 ct., respectively. They are also still available for institutional use in the free distribution, and within the limits of the supply the needs of teaching and research departments and similar agencies will be met on direct application to the Office of Experiment Stations, U. S. Department of Agriculture.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical researches of the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 171, 172).—This work has included investigations into the chemistry of the tobacco plant, work on the determination of purine nitrogen in leaves and on the determination of glutamine, investigation of the metabolism of amides (especially glutamine and asparagine) in tobacco leaves, and work on improvements in the methods for isolating the dicarboxylic amino acids from the products of protein hydrolysis.

[Chemical investigations at the Nebraska Station] (*Nebraska Sta. Rpt.* [1936], p. 8).—The report contains concise notes on the preparation and study of the cereal glutelins and enzymes of wheat flour as related to flour grade and baking characteristics.

Electrokinetics.—XVI, Streaming potential in small capillaries, H. B. BULL and L. S. MOYER (*Jour. Phys. Chem.*, 40 (1936), No. 1, pp. 9–20, figs. 4; *abs. in Minnesota Sta. Rpt.* 1936, p. 16).—Conditions in a membrane are considered in this contribution to a series from the Minnesota Experiment Station (E. S. R., 75, p. 582) in relation to the measurement of the streaming potential.

The equation for the potential between two coaxial cylinders has been substituted for the conventional plate condenser equation in the case of small pore radii. J. Lens' ¹ modification of the thickness of the double layer in thin slits has been introduced into this equation, and the critical value of the radius has been estimated by this method. These equations have been compared with the critical radius calculated from S. Komagata's ² equations. It is found that the two sets of equations do not yield concordant results except when the radius is large. The change in the viscosity of water with capillary size has been considered. The electrical "counterpressure" has been compared with the mechanical pressure, and an equation expressing this relationship has been derived. A method for obtaining the average pore radius has been developed and tested. The theoretical critical pore radius has been compared with those actually found in diaphragms. The two values do not agree in the case of quartz and glass. Anomalies in the zeta-concentration and flow-concentration curves of quartz diaphragms with pores below the critical point are noted. These curves are compared with those given by cellulose, which behaves in a normal manner.

Electrokinetics.—XVII, Surface charge and ion antagonism, L. S. MOYER and H. B. BULL (*Jour. Gen. Physiol.*, 19 (1935), No. 2, pp. 239–247, figs. 5; *abs. in Minnesota Sta. Rpt.* 1936, p. 15).—The question of the critical pore diameter for streaming potential is discussed in a further contribution to this series.

The surface charge is calculated for cellulose in contact with solutions of K_3PO_4 , K_2CO_3 , K_2SO_4 , KCl , and $ThCl_4$. The surface charge of cellulose in contact with a solution of 2×10^{-4} N $NaCl$ is calculated as a function of tempera-

¹ Roy. Soc. [London], Proc., Ser. A, 139 (1933), No. A 839, pp. 596–603, figs. 3.

² Electrotech. Lab., Tokyo, Japan, Res., No. 362 (1934), pp. [3] + 49, figs. 16.

ture and is found to show a sharp break at 39° C. This is interpreted in terms of the change of the specific heat of water. A marked ion antagonism is found in NaCl:KCl, KCl:MgCl₂, NaCl:MgCl₂, NaCl:CaCl₂, KCl:CaCl₂, CaCl₂:MgCl₂ mixtures when the surface charge is calculated as a function of concentration.

Molecular dimensions from viscosity studies, R. M. THEIS and H. B. BULL (*Jour. Phys. Chem.*, 40 (1936), No. 1, pp. 125-131, figs. 2; *abs. in Minnesota Sta. Rpt. 1936*, p. 17).—The authors report in this contribution from the Minnesota Experiment Station certain difficulties encountered in the application of generalized equations to a specific case of data obtained in a study of the lecithin molecule.

Physico-chemical studies on lecithin, H. B. BULL and V. L. FRAMPTON (*Jour. Amer. Chem. Soc.*, 58 (1936), No. 4, pp. 594-596, figs. 2; *abs. in Minnesota Sta. Rpt. 1936*, p. 17).—This contribution from the Minnesota Experiment Station reports upon a study of lecithin-cephalin mixtures prepared from eggs.

The importance of the effect of cephalin upon the isoelectric point was brought out. The isoelectric point is plotted as a function of the amino nitrogen content. The curve is extrapolated to zero amino nitrogen content and yields an isoelectric point of 6.4 for lecithin.

The change of the isoelectric point with time was also studied, and titration curves for lecithin suspensions are reported.

The lipids of the wheat embryo, I, II, B. SULLIVAN and C. H. BAILEY (*Jour. Amer. Chem. Soc.*, 58 (1936), No. 3, pp. 383-390; 390-393; *abs. in Minnesota Sta. Rpt. 1936*, p. 23).—The two papers here noted open a serial contribution from the Minnesota Experiment Station.

I. *The fatty acids*.—This records the observations that saturated fatty acids constituted 16 percent of the total fatty acids of wheat embryo lipides and consisted largely of palmitic acid, together with smaller amounts of stearic and lignoceric acids, and that unsaturated fatty acids, representing 84 percent of the total fatty acids, were divided approximately as follows: α - and β -linolenic acids 3.55 percent, α - and β -linolic acids 52.31 percent, and oleic acid (by difference) 28.14 percent. No fully saturated glycerides were encountered in these lipides, the latter being composed of mixed, unsaturated-saturated glycerides, some tri-unsaturated glycerides, and an unidentified carbohydrate.

II. *The unsaponifiable fraction*.—This reports that the unsaponifiable fraction of the wheat embryo amounts to about 4 percent. Approximately 70 percent of this fraction consists of a mixture of sterols, about 56 percent of which occur in the free state. Measurements of unsaturation of the sterol fraction by per acids show the presence of an unsaturated sterol with at least two double bonds in addition to the isomeric sitosterols and dihydrositosterol. Determination of unsaturation on sterols by iodine values was found to be unreliable. The nonsterol fraction of the unsaponifiable material required 2.91 percent available oxygen. Preliminary work on this fraction indicates the presence of polyene hydrocarbons as well as an alcohol.

Water absorption of spray and roller dried milks, O. SKOVHOLT and C. H. BAILEY (*Northwest, Miller and Amer. Baker*, 12 (1935), No. 8, pp. 358, 359, 394; *abs. in Minnesota Sta. Rpt. 1936*, p. 18).—This contribution from the Minnesota Experiment Station reports upon experiments in which particle size of roller process milk was determined by a sedimentation method and found to be substantially larger than typical spray process milk. Viscosity of reconstituted roller milk, as determined by a capillary viscometer, was also appreciably greater than reconstituted spray process milk. The former decreases in viscosity as the preparation stands for a time, whereas the latter changes only slightly. The batters made with flour and dried milks were then prepared,

and those made with roller process milk proved to be more viscous than when spray process milk was employed, but when the proportion of water was reduced the reverse was the case as was also true with doughs. Accordingly the viscosity of their mixtures may not correlate with the water absorption registered by dry milk when used in an ordinary dough and particularly when comparing spray and roller milks.

Chemical nature of citrin. V. BRUCKNER and A. SZENT-GYÖRGYI (*Nature [London]*, 138 (1936), No. 3503, p. 1057).—Further work on the crystalline flavone fraction of lemon juice capable of curing disorders of the capillary wall and termed citrin has shown it to consist of mixed crystals of two different dyes. One of these, hesperidin, m. p. 261° [C.], forms the major part of citrin, but the activity and color reactions are due to the other component, eriodictyol glucoside, a demethylated hesperitin. The active eriodictyol glucoside was not found in any considerable quantity in unripe oranges, while hesperidin was present in considerable amounts. The probability is suggested that eriodictyol glucoside is formed from hesperidin by demethylation during the ripening of the fruit.

Studies on biological oxidations.—VII, The oxidation of ascorbic acid in biological fluids, E. S. G. and A. G. BARRON and F. KLEMPERER (*Jour. Biol. Chem.*, 116 (1936), No. 2, pp. 563–578, figs. 3).—In continuation of a series of papers, some of which have been noted (E. S. R., 75, p. 741), a comparison is reported of the rate of oxidation of ascorbic acid in two classes of biological fluids. In one of these inhibitory mechanisms protecting ascorbic acid from oxidation appear to be present, while in the other ascorbic acid is oxidized at a measurable speed attributed to the presence of acid-oxidizing enzymes. An effort was also made to discover the nature of the protective action in the first group and the oxidizing catalysts in the second. Similar methods were followed as in the fifth study of the series, care being taken to avoid contamination of the fluid by heavy metals.

The rate of oxidation of ascorbic acid in fluids of the first group was determined with and without the addition of CuCl_2 . The fluids of animal origin tested included blood serum, cerebrospinal fluid, urine, saliva, and gastric juice of man; whole blood of dog; aqueous vitreous humor of cattle; and cow's milk; and of vegetable origin, orange, tomato, and grapefruit juices. In the absence of added catalysts all these fluids protected in varying degrees the oxidation of added ascorbic acid, the protection being complete with gastric juice, milk, and orange, tomato, and grapefruit juice. When CuCl_2 was added the greatest protective power was shown by blood serum, milk, and tomato juice and the least by urine, saliva, and grapefruit juice. It was demonstrated that glutathione, proteins, and amino acids (by the formation of un-ionized copper complexes) are the most important mechanisms for the protection of ascorbic acid in the biological fluids possessing such inhibitory action.

As representative examples of the group of biological fluids possessing no inhibitory mechanism, juices extracted from apples, cabbage, yellow squash, peaches, and water cress were selected. Because of the low buffering power of these fluids the ascorbic acid was previously neutralized by sodium carbonate. The most rapid oxidation of ascorbic acid occurred with yellow-squash juice, followed by the juices of lettuce, peaches, cabbage, apples, and water cress. In order to determine the catalysts responsible for the oxidation of ascorbic acid in these fluids, two types of inhibitors were used—(1) HCN which inhibits oxidations produced by hemochromogens and (2) 8-hydroxyquinoline which inhibits those produced by copper. The oxidation produced by the juices of cabbage, yellow squash, and water cress was the same with and without 8-hydroxy-

quinoline, showing that the oxidation in these biological fluids was not due to copper catalysis. The oxidation of the juice of apples, lettuce, and peaches was found to be partly due to copper. HCN inhibited 90 percent of the oxidation produced by yellow squash and only 50 percent of the oxidation by cabbage juice, but the addition of CuCl_2 did not increase appreciably the rate of oxidation. Glutathione failed to inhibit the oxidation by yellow squash.

It is concluded that hemochromogens are probably the chief catalysts for the oxidation of ascorbic acid in those biological fluids possessing no inhibitory mechanism.

The catalytic oxidation of ascorbic acid, A. E. KELLE and S. S. ZILVA (*Biochem. Jour.*, 29 (1935), No. 5, pp. 1028-1035).—The spontaneous oxidation of ascorbic acid in tap water, ordinary laboratory distilled water obtained from a tin-lined copper still, water redistilled from glass apparatus, and water distilled from and received in quartz apparatus was investigated by indophenol titration of solutions of *l*-ascorbic acid prepared by dissolving 15 mg of the acid in 40 cc of water and adjusting the pH to 7.4 by the addition of sodium hydroxide. The flasks containing the solution were kept at 37° C. and 5-cc samples withdrawn at various intervals for the test. The results obtained are summarized as follows:

"Ordinary laboratory distilled water contains sufficient quantities of metals (copper and iron) to catalyze the irreversible oxidation of dissolved ascorbic acid. In the very early stages of the process dehydroascorbic acid is found in quantities almost equivalent to the amounts of ascorbic acid which are oxidized, but as the reaction proceeds the quantities of the dehydrogenated acid present diminish. This catalytic action is barely perceptible when the vitamin is dissolved in water which has been redistilled several times from glass apparatus and which is used immediately or in water distilled from and received in quartz. When this water is previously saturated with oxygen the disappearance of ascorbic acid is not significantly increased. The addition of aqueous extracts of liver, kidney, muscle, spleen, large and small intestine and of plasma, intact or hemolyzed erythrocytes, and $\text{N}/10$ NaCl inhibits the oxidation of ascorbic acid in ordinary distilled water or in water to which iron or copper has been added. Leucocytes have no influence on the oxidation. There is a disappearance of ascorbic acid immediately after the addition of hemolyzed erythrocytes which is proportional to the quantity of the added corpuscles. This disappearance does not take place when the hemolyzed corpuscles are previously treated with carbon monoxide. It is suggested that dehydroascorbic acid has to be reduced in the organism before it can exercise antiscorbutic activity."

The interaction of peroxidase and ascorbic acid (vitamin C) in biological oxidations and reductions, H. TAUBER (*Enzymologia*, 1 (1936), No. 4, pp. 209-212).—A method is described for the preparation of a peroxidase solution from horseradish which is capable of rapidly oxidizing ascorbic acid. The activity of the undialyzed peroxidase solution remained after 6 mo. of storage in the cold. After dialyzing, the solution changed from light brown to colorless and lost all of its ascorbic acid oxidizing property. The addition of small amounts of quinone-forming compounds, such as vanillin and *p*-phenylenediamine, and a cold extract of suprarenal glands restored the activity.

Absorption rate of oxygen by orange juice: Effect of catalysts, C. W. EMMY (*Indus. and Engin. Chem.*, 28 (1936), No. 4, pp. 480-483, figs. 2).—In this contribution from the U. S. D. A., Bureau of Chemistry and Soils, a study was made at Los Angeles, Calif., of the part played by oxygen in the oxidation of the ascorbic acid contained in orange juice and the effect of each of four

catalysts on the reduction process. In the presence of oxygen the ascorbic acid content of California Valencia orange juice diminished, and when the reducing factor disappeared the absorption of oxygen practically ceased. The oxygen absorption was accelerated by the presence of 20 p. p. m. of copper salts, to a less extent by zinc, and to a slight extent by stannous and stannic salts. Approximately the same rate of absorption and a proportionate increase in the absorption of oxygen resulted when an ascorbic acid preparation was added to the filtered orange juice.

A note on the reversible enzymic oxidation of d-glucO-ascorbic acid, S. S. ZILVA (*Biochem. Jour.*, 30 (1936), No. 7, p. 1215).—It is noted briefly that inactive d-glucOascorbic acid can also be dehydrogenated by the enzyme previously shown to be present in apple juice and capable of dehydrogenating l-ascorbic acid.² "The experiment, therefore, suggests that the enzymic dehydrogenation of these compounds takes place independently of their stereochemical structure and of their biological activity."

Duality of the reversibly oxidized forms of vitamin C and the polarization of its dienol group, N. BEZSSONOFF and M. WOLOSZYŃ (*Nature [London]*, 139 (1937), No. 3515, p. 469).—The reversible behavior of the blue and green solutions obtained by treating ascorbic acid with phosphomolybdic acid is described. It is noted that phosphomolybdic acid gives identical color reactions with hydroquinol but not with pyrogallol or various other polyphenols. With catechol, which resembles ascorbic acid in having the group COH:COH, a distinct yellow color is produced. It is concluded that the dienol groups of vitamin C and hydroquinol are subject to a common influence, polarization, which does not distinguish the enol groups of catechol or pyrogallol.

The chemical nature of "ascorbic acid oxidase", E. H. STOTZ, C. J. HARBER, and C. G. KING (*Science*, 86 (1937), No. 2219, p. 35).—In this brief preliminary report evidence leading to the conclusion that the action of so-called enzymes in catalyzing aerobic oxidation of vitamin C can be fully explained by the catalytic action of copper is summarized as follows:

"The copper content of the 'enzymes' from squash and cauliflower is sufficient to account for the observed catalysis, and the greater part of the Cu in such preparations is found in the coagulated protein upon heat inactivation; mixtures of copper salts with albumin exhibit properties like those of the postulated enzymes with respect to catalysis, inhibition, heat and acid activation, optimum pH and stability; seven different copper inhibitors, both organic and inorganic, have the same relative effects upon pure copper compounds, copper-protein mixtures, and the enzymes; copper biuret exhibits a catalytic effect that is equivalent, atom per atom, to that of simple copper salts."

In view of these findings the authors suggest that "there is no further need for using such terms as ascorbic acid oxidase, 'vitamin C oxidase', and 'hexuronic oxidase' in the literature, at least in the sense that they have been used in the past."

A study of "ascorbic acid oxidase" in relation to copper, E. Stotz, C. J. Harber, and C. G. King (*Jour. Biol. Chem.*, 119 (1937), No. 2, pp. 511-522, figs. 3).—This is the complete report, with experimental data, of the investigation noted above from a preliminary report.

The determination of ascorbic acid as furfural and a comparison of results obtained by this method and by indophenol titration, J. H. ROE (*Jour. Biol. Chem.*, 116 (1936), No. 2, pp. 609-619).—"A method for the determination of

² *Biochem. Jour.*, 28 (1934), No. 2, pp. 663-666, fig. 1.

ascorbic acid as furfural has been developed for plant and animal tissues. The method consists essentially of the determination of the furfural formed by boiling an acid extract of a tissue in which the ascorbic acid has been oxidized, by passage through norite, with HCl alone and with HCl containing SnCl_2 . The value obtained with the HCl- SnCl_2 mixture minus that given with HCl alone is the amount of furfural from ascorbic acid. Furfural is determined by the color formed with aniline, stabilized with SnCl_2 , and proper amounts of acetic acid."

Data are reported on the recovery of ascorbic acid when added to vegetable and animal tissue and on the comparative ascorbic acid values obtained by the furfural and indophenol methods. The recoveries were considered quantitative, the range being from 94 to 105 percent. The results obtained by the two methods agreed within the limits of experimental error for every material tested except liver, the indophenol value for which was 25 percent higher than the furfural value. The close agreement in values obtained by the two methods is thought to indicate that ascorbic acid exists in both plant and animal tissues in the reduced form.

"The furfural colorimetric method is of value for its high degree of specificity, for the determination of ascorbic acid in tissues to which the indophenol titration procedure may not be applied, and as a method for determining dehydroascorbic acid."

The availability of the carbohydrates and fats of the green leaf, together with some observations on crude fiber, M. K. HOBWITT, G. R. COWELL, and L. B. MENDEL (*Jour. Nutr.*, 12 (1936), No. 3, pp. 255-273).—In continuation of the study noted on page 722, the authors present a method for determining the available carbohydrate of a food, based upon the ability of an active maltase which converts maltose to glucose if the concentration of maltose in the substrate is not more than 0.25 g per 100 cc. A commercial preparation of takadiastase, which will liquefy 2,700 times its weight of starch in 10 min. and which contains little if any reducing sugar, was used in the tests. The enzymatic procedure for determining the crude fiber of spinach when compared with the A. O. A. C. method (E. S. R., 76, p. 747) yielded residues more than 3 times as much as those obtained by successive treatment with acid and alkali characteristic of the conventional crude fiber method.

A method is presented for estimating the true fat content of the ether-soluble fraction of a food material. When applied to spinach more than 55 percent of the material obtained by ether extraction and sometimes called "fat" was found to be indigestible.

A simple method for the detection of copper in alloys, B. L. HERRINGTON and J. G. BREBETON (*Jour. Dairy Sci.*, 20 (1937), No. 4, pp. 197, 198).—This note from the [New York] Cornell Experiment Station describes a simple test method based on the fact that copper chloride imparts characteristic blue and green colors to a nonluminous flame. The test paper consists of fine sand-paper strips impregnated with pure ammonium chloride. The metal to be tested is rubbed with a strip of the test paper until a black smudge appears on the rough surface. The smudge end of the paper is then burned in a non-luminous flame (bunsen or alcohol lamp). When the yellow flame caused by the burning paper disappears the flame next to the charred end of the paper will be tinged azure blue if copper is present. This test has given good results even in the hands of amateurs.

Dissimilation of glucose by heterofermentative lactic acid bacteria, M. H. NELSON and C. H. WERKMAN (*Jour. Bact.*, 30 (1935), No. 6, pp. 547-557).—Carbon and oxidation-reduction balances for the fermentation of glucose by three

species, representative of the heterofermentative lactic acid bacteria, were determined in an investigation carried out at the Iowa Experiment Station.

"Lactic, acetic, and carbonic acids, ethyl alcohol, and glycerol were found as end products. The millimols of carbon dioxide produced were equivalent to the sum of the acetic acid and ethyl alcohol. The glycerol produced was equivalent to twice the millimols of acetic acid."

A probable series of breakdown products in the dissimilation of glucose by the heterofermentative lactic acid bacteria is suggested.

AGRICULTURAL METEOROLOGY

Weather rambles, W. J. HUMPHREYS (*Baltimore: Williams & Wilkins Co., 1937, pp. [5] + 265, [figs. 37]*).—Keen observations on weather in some of its unusual moods and manifestations, as well as on some of the commoner but not necessarily better understood phenomena of dew, rain, frost, snow, drought, and wind and dust storms, are discussed in this pleasantly discursive but none the less soundly scientific little book.

World weather, VI, G. T. WALKER and E. W. BLISS (*Mem. Roy. Met. Soc. 4 (1937), No. 39, pp. 119–139, figs. 19*).—This is a continuation of previous studies (*E. S. R., 69, p. 13*), dealing primarily with the winter seasons of the North Atlantic and North Pacific Oceans and with winter and summer seasons of the southern oscillation. In the previous studies fluctuations of pressure, temperature, and rainfall in the winter in the region of the North Atlantic were studied as a connected system. In the study here reported a similar system is "shown to hold in the spring, summer, and autumn. But the amount of persistence is small, so that the results are of little value for foreshadowing weather; nor does a consideration of the trade wind region lead to success in this respect. Similarly the southern oscillation which was found active in the summer and winter seasons over a large part of the globe is now shown to function in the two remaining seasons, and, while that of March to May has little control over the following quarter, the southern oscillation of September to November has a correlation coefficient of 0.9 with the oscillation of December to February. Thus there are a number of relationships of between 0.6 and 0.82 available for foreshadowing weather."

Snow structure: Some practical applications, G. SELIGMAN (*Quart. Jour. Roy. Met. Soc. [London], 63 (1937), No. 268, pp. 93–103, pls. 6, figs. 2*).—This article explains the characteristic structure of snow and influences affecting its formation and behavior. It is stated that "it is only of recent years that a systematic study of snowcraft has been taken up, and much work in a rich field lies ahead of the investigator. The newly formed International Commission of Snow has as one of its objects the encouragement of a scientific study of these and kindred questions and the dissemination of the knowledge so obtained."

The nature of snow, G. SELIGMAN (*Roy. Inst. Gr. Brit. Proc., 29 (1936–37), pt. 3, No. 138, pp. 463–483, pls. 6*).—Substantially noted above.

Snow surveys for the purpose of forecasting stream flow, R. C. FARROW (*Forestry Chron., 13 (1937), No. 1, pp. 271–283, pl. 1, figs. 5*).—The degree of success attained in snow surveys in southern British Columbia as a means of forecasting water supply for irrigation, power, and other purposes is reported upon in this article. Conditions which militate against the accuracy and reliability of the forecasts are also discussed.

Areas of intense drought distress, 1930–1936, F. D. CRONIN and H. W. BEERS (*Works Prog. Admin. [U. S.], Div. Social Res., Res. Bul. 1, 5. ser. (1937)*),

pp. IV+54, figs. 8).—This article, the first of a series of three reports, gives in some detail the results of a study of social aspects of the drought problem cooperatively made by the Division of Social Research of the Works Progress Administration, the U. S. D. A. Bureau of Agricultural Economics, and the Resettlement Administration. It is stated to be a preliminary effort to delineate areas of varying degrees of drought intensity and to select carefully defined sections as the basis for further study. It deals in general with the problem of drought and describes conditions as related to drought in the Great Plains region. It discusses drought incidence in the Great Plains region, misdirected agricultural expansion, the measure of drought effect, rainfall, crop conditions, pasture conditions, number of cattle, Federal aid, combined indices of drought intensity, and type-of-farming areas. The area studied included all or parts of Colorado, Iowa, Kansas, Minnesota, Missouri, Montana, Nebraska, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, and Wyoming.

Climatological summary for 1935, C. A. PATTON (*Ohio Sta. Bul. 579 (1937)*, pp. 133-139).—The usual tabular summaries of data on temperature, precipitation, and frost-free periods are given for the station at Wooster and for Ohio in general. Extremes of rainfall and temperature characterized weather at the station during the year. Rainfall in April was the least and in July and August the greatest on record in 48 yr. The total precipitation, 46.32 in., for the year was the greatest since 1913. The average temperature for the year was 49.6° F., which is very close to the normal. The highest temperature was 98° July 19, the lowest -8° December 31. The last killing frost in the spring was on April 18, the first in autumn on September 30, giving a growing season of 165 days. The number of clear days was 130. The total snowfall was 30.2 in.

SOILS—FERTILIZERS

[Soil investigations at the New Haven Station] (*Connecticut [New Haven] Sta. Bul. 393 (1937)*, pp. 194-199).—These have included work on the soil erosion survey, nitrogenous fertilizer and soil acidity, potato soils in Connecticut, agronomic significance of soil tests, relation of site quality of oak stands to soil properties, benefits of litter cover for soil structure, effect of fertilizing tree seedlings, and soil fertility experiments with vegetable crops, including effect of soil amendments on sandy plats.

[Soil investigations, Nebraska Station] (*Nebraska Sta. Rpt. [1936]*, pp. 16-19).—Soil moisture; restoration of organic matter in soils; nitrification in Nebraska soils; influence of commercial fertilizers, manure, and lime on yields on Carrington clay loam; factors affecting permeability of soils, including subsoiling tests; and availability of phosphorus in alkaline soils are briefly dealt with.

The nature and properties of soils, T. L. LYON and H. O. BUCKMAN (*New York: Macmillan Co., 1937*, 3. ed., pp. XIII+392, figs. 45).—The present edition of this widely known textbook, prepared at Cornell University, differs but little from that of 1929 (E. S. R., 62, p. 810), which is here brought up to date.

The contents are: A fundamental concept of the soil; the supply and availability of plant nutrients in mineral soils; the physical properties of mineral soils; colloidal clay and ionic exchange; the organisms of the soil; the organic matter of mineral soils; forms of soil water and their plant relations; soil-moisture losses and their control; the origin and classification of soil materials; soil formation, classification, and survey; the nature and utilization of organic soils; the soil reaction—soil acidity and alkalinity; liming the soil;

the nitrogen economy of soils; fertilizers and fertilizer practice; farm manure and green manure; the methods of fertility maintenance for mineral soils; author index; and subject index.

Soil conditions and plant growth, E. J. RUSSELL (*London and New York: Longmans, Green & Co., 1937*, 7. ed., pp. VIII+655, pl. 1, figs. 65).—The author notes in his preface to the present edition that in visits to many European experiment stations, including those of Poland and Russia, and also from papers and discussions of the Third Congress of the International Society of Soil Science and from other sources, "I have accumulated a considerable amount of material, and I have selected from it whatever seemed suitable for the present edition [E. S. R., 67, p. 108]. The changes are so considerable that much of the book has had to be rewritten."

To make space for the new material, reduction has been effected in some other parts of the book, as "it is intended to be read, not merely consulted like a dictionary." The appendix on analytical methods has been replaced by a brief list of references to sources of the necessary methods. The bibliography has been curtailed rather than enlarged, in view of the present availability of bibliographies more complete than an appendix to such a textbook could contain.

Land classification in Wisconsin, A. R. WHITSON (*Amer. Soil Survey Assoc. Bul. 16 (1935), pp. 39-41, figs. 3*).—A note contributed from the Wisconsin Experiment Station proposes four grades of productivity for staple food crops; the further consideration in land grading of climatic factors; a four-grade, semi-quantitative classification with respect to stoniness; a slope classification into lands of less than 10 percent, from 10 to 15, from 15 to 30, and more than 30 percent; and a grading with respect to degree of erosion. On the basis of these criteria, it was found possible to set up four grades of general land value for agricultural use. Choice of lands for forestry is made on a separate and quite different basis.

A pedologic study of some soils in New Jersey, J. S. JORFFE (*Soil Sci., 43 (1937), No. 3, pp. 221-238*).—In a contribution from the New Jersey Experiment Stations the author discusses some relations of the geographic-geologic features, the topography, and the climate of a number of soil profiles in New Jersey.

The variations in the depth of the profiles and the constitution of 13 soils are analyzed pedologically, and the agrological inferences are discussed; the relation of the erosion problem to the profile constitution is noted; chemical analyses of 13 soil profiles are discussed in the light of the processes involved in the formation of these profiles; and some agrological aspects of the profile studies are taken up with special reference to calcium, magnesium, and phosphorus.

The variety of solonetz red soils in the vicinity of the village of Marcopoulo, Attica, K. I. NEVROS and I. A. ZVORYKIN (*Soil Sci. 43 (1937), No. 3, pp. 239-246*).—"In the vicinity of the village of Marcopoulo there is a solonetzic CaCO_3 -free red soil of very ancient origin in which the soil-forming process is directed toward laterization, as is indicated by the total analyses of the soil and the clay. The soil-forming process here is complicated by the influence of absorbed Na.

"The solonetzic properties of the soil are apparent from the morphologic study of the profile and are strongly marked in the structure of horizons B and B_1 . Horizon A_1+A_2 is also very typical of a solonetzic soil, being considerably bleached and impoverished of the clay fractions when compared with the underlying horizons. The dark spots and smears, as well as the occasional

small dark concretions and the light gray veins, prove the influence of the ground waters on the process of soil formation. The existence of this influence is confirmed by the considerable quantities of absorbed Na, as well as by the presence of chlorides and sulfates, found in the water extract. Thus this is an example of 'underground' salinization of red soil. The process of natural desalinization has progressed appreciably, and apparently this is a case of solonetz solodization. This is, therefore, a relic formation."

Water-supplying power and water-absorbing power of soils as related to wilting of wheat and coleus in greenhouse pot cultures, B. E. LIVINGSTON and W. L. NOREM (*Soil Sci.*, 43 (1937), No. 3, pp. 177-204, figs. 5).—Extending a number of previous investigations by Livingston (E. S. R., 38, p. 522) and various coworkers, the authors now state a part of their current observations of advanced wilting and of soil conditions associated with it as follows:

"Our numerical results with soil-point cones furnish additional support to the conclusion that that instrument promises to be exceedingly useful whenever the dynamic water relations between plant and soil are to receive attention. It is again emphasized that ordinary plants respond, in their subterranean water relations, directly to the water-supplying power of the soil adjacent to their absorbing roots, rather than to soil suction or to soil-moisture content referred to moisture equivalent, water-holding capacity, hygroscopic coefficient, or other such static soil characteristics that represent internal soil surface, etc. Of course these static characteristics of a soil determine its water-supplying power at any specified temperature, but supplying power is the environmental feature that directly limits the rate of water absorption and it may be measured and studied quantitatively for the purposes of physiology without reference to the static characteristics of the soils considered.

"The attainment by a drought-affected plant to a critical stage of wilting, such as the onset of permanent wilting, is again shown as corresponding to a critical water-supplying-power value of the soil about the roots—a value that is essentially the same for soils of greatly different static properties. When the coleus and wheat plants of these experiments were all in essentially the same advanced stage of wilting, the water-supplying power at the 5-7-cm depth was essentially the same for the sixteen different soil mixtures studied whether the soil was light or heavy, whether its volumetric water-holding capacity was 50 percent or above 90 percent.

"Some evidence was found, however, to support the proposition that soil composition with reference to loam, humus, and sand content, which is a static soil feature, may in some instances exert a very minor influence on the critical water-supplying-power value that corresponds to a critical advanced stage of plant wilting. That proposition is not yet well established and it calls for further study.

"A new device for quantitatively estimating the water-absorbing power of a soil mass at any desired depth and from time to time, without disturbing the soil after the instrument is installed, proved highly promising. A Livingston porous-porcelain irrigator cone [E. S. R., 41, p. 631] remains permanently in the soil, at any specified depth. It is temporarily filled with water for a short time while each reading is being made, but it remains empty at other times. Readings of the rate of water loss for 1 hr. are obtained by means of a burette, a mercury barostat being introduced between burette and cone. For the critical stage of wilting considered, there was generally a constant proportionality between water-absorbing-power readings of the irrigator device at the 9-15-cm depth and corresponding water-supplying-power readings of soil-point cones at the 5-7-cm depth."

Some soil moisture relationships of the Wooster silt loam, R. BRADFIELD and F. S. HOWLETT (*Ohio Sta. Bul. 579 (1937), pp. 30, 31*).—Data are concisely summarized.

Electrodialysis and cation exchange studies on soils of varying organic matter content, A. L. PRINCE and S. J. TOTH (*Soil Sci., 43 (1937), No. 3, pp. 205-217*).—The authors report from the New Jersey Experiment Stations an investigation of the effect of the content of organic matter upon titratable acids and bases, upon ultimate pH, upon cation exchange capacity, and upon mobilization of iron and silica.

It was shown that "the quantity of bases electrolyzed is not a function of the pH of the field sample, but rather depends upon the total cation exchange capacity and the degree of base saturation. The total dialyzable acids and bases were greater on the limed than on the unlimed plats, and still greater on those plats receiving manure and lime. The bulk of the bases and acid were delivered in 14 hr.

"The addition of organic matter and phosphorus to the soil increased the acidoid-basoid ratio of the soil complex, and consequently lowered the ultimate pH and increased the cation exchange capacity. Thus the plats receiving manure showed a decrease of approximately 0.4 to 0.6 pH unit and an increase in cation exchange capacity of about 4 m. e. [milliequivalent] per 100 g. of soil. Mobilization of iron and silica increased with decreasing ultimate pH.

"Electrodialysis reduced the cation exchange capacity of all samples, the greatest loss occurring with the samples from plats receiving manure and lime. This was explained on the basis that during electrodialysis acidoids were hydrolyzed, and also that a certain fraction of the soil complexes mobilized and precipitated in the cathode chamber. The average silica-iron ratio in the dialyzate from the anode was higher than that from the cathode. The degree of the decomposition of the organic matter was found to influence the colloidal properties previously listed, i. e., with the cylinder soils receiving undecomposed rye straw only slight effects were noted. It was found that after electrodialysis a pH gradient varying from 4.3 near the anode to 5.0 at the cathode existed in the soil compartment. An analysis of the sediment appearing in the cathode dialyzates showed that the material was predominantly basic and had a low cation exchange capacity. Organic matter and manganese, as well as appreciable quantities of calcium and magnesium, were also found in the sediment."

Behavior of legume bacteria (*Rhizobium*) in relation to exchangeable calcium and hydrogen ion concentration of the colloidal fraction of the soil, T. M. MCCALLA (*Missouri Sta. Res. Bul. 256 (1937), pp. 44, pls. 6, figs. 14*).—A bacteriological medium which simulated soil conditions was prepared by use of electrolyzed colloidal clay. The conditions were thus made chemically and bacteriologically controllable and were very similar to soil conditions.

"In the presence of an ample supply of calcium, normal legume bacteria remained normal and abnormal or so-called variant forms became normal. All of these, after growth with ample calcium, gave good nodulation on plants supplied with calcium. In the absence of calcium, the normal legume bacteria became abnormal, and the abnormal forms remained abnormal. Both failed to nodulate the host plant. The best nodulation was secured when both the bacteria and the plants were given calcium. No nodulation occurred when neither the bacteria nor the plants received calcium." The order of importance of the elements named as nutrients for legume bacteria appeared to be as follows: Ca-Mg-Ba-K-H. Growth of the bacteria was related to the amount of calcium

present in the media. For the best growth of the legume bacteria it was necessary to have the clay at least 50 percent saturated with calcium.

Anaerobic bacteria capable of fermenting sulfite waste liquor, A. M. PARTANSKY and B. S. HENBY (*Jour. Bact.*, 30 (1935), No. 6, pp. 559-571).—Five new species of the genus *Clostridium* were isolated from water-covered muds and a soil sample and named *C. polyfermenticum* (nine strains), *C. saccharophilicum* (three strains), *C. saccharopetum* (one strain), *C. saccharopostulatum* (two strains), and *C. sartagoformum* (three strains).

"Taken as a group the new species are characterized by their unusually diversified and vigorous saccharolytic action and by the complete absence of any proteolytic action. . . . Their most outstanding characteristic is the ability to grow in and ferment s[ulfite] w[aste] l[iquor] in dilutions up to 40 to 50 percent of liquor, when the latter contains some nitrogenous material, e. g., 0.2 percent beet extract. Butyric and acetic acids and considerable amounts of gas are produced under these conditions.

"Morphologically *C. polyfermenticum*, *C. saccharophilicum*, *C. saccharopetum*, and *C. saccharopostulatum* resemble each other closely, but differ markedly in this respect from *C. sartagoformum*. They are best distinguished from one another on the basis of colony characteristics and, particularly, on the basis of their fermentation reactions."

Sampling soil for the pH determination, A. H. EDDINS and W. H. SCOVILLE (*Soil Sci.*, 43 (1937), No. 3, pp. 219, 220, fig. 1).—The authors describe a tool designed for the sampling of Florida sands. The sampling tube proper consists of two longitudinal segments of 1½-in. steel tubing hinged together by a bolt and so attached to the spring-steel loop handle that the blades open for the release of the sample when the handle is compressed. The blades are sharpened at their opened ends to facilitate penetration of the soil.

"The sampler and the procedure described for the preparation of the samples for the pH determination are particularly adapted for use in those sections of the country where the soils are similar to the sandy types of Florida, but could not be used successfully where the soils have a clay texture or contain gravel or stones."

Comparison of various chemical quick tests on different soils, M. S. ANDERSON and W. M. NOBLE (*U. S. Dept. Agr., Misc. Pub.* 259 (1937), pp. 24, figs. 3).—"Comparable tests were made upon a group of widely diversified soils with several of the widely used commercial soil-testing sets. The soils used were virgin samples of Barnes silt loam, Carrington silt loam, Clinton silt loam, Miami silt loam, Cecil clay loam, Ruston loamy sand, and Caribou loam. The tests, made independently by two operators, were for available phosphorus and potassium and for acidity, lime requirement, and nitrates. The sets used were the Simplex, Emerson, LaMotte, Sudbury, and Hellige, and the test sets made by the Urbana [Illinois] laboratories and that made and used by the Indiana . . . Experiment station. Some of the laboratory tests not used commercially were included. The results obtained by two observers with the same set on a particular soil were in fairly good agreement, but results by different methods on the same soil were in much poorer agreement." The data show the general trend of results that may be expected when different test sets are used on various soils. No study of actual crop response on these soils when treated to correct the indicated deficiencies was attempted.

"In many State experiment stations chemical tests have been found a valuable aid for the diagnosis of soil needs when interpreted by trained agronomists in possession of information regarding the response of various crops grown on different local soils after application of fertilizers. The use of any one of

these tests is neither recommended nor condemned. They are thought to be of particular value under certain circumstances, but the scope of their usefulness is not yet clearly defined. . . . It is realized that further investigations must be made, especially of diversified soils growing crops in response to various fertilizer treatments."

The variance of methods of testing for phosphorus on soils previously treated with different phosphate fertilizers, M. F. MORGAN (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 45-51).—At the Connecticut [New Haven] Experiment Station the author carried out a comparative investigation of various methods for testing the availability of phosphatic fertilizers after these fertilizers had been for some time in contact with the soil. The results were checked by control experiments with two tobacco crops in pots.

The author found, in part, that "both the Truog procedures [E. S. R., 64, p. 312] and the extraction with $N/2$ acetic acid showed highest availability from rock phosphate, although this material was quite unavailable on this soil as measured by crop response. All of these extracting solutions are 3 pH or lower in acidity and are thus capable of dissolving large amounts of phosphorus from such a substance, although in the soil it has remained inert. The writer's usual method of passing the Universal soil extracting solution [E. S. R., 73, p. 746] directly through the soil mass has given results in better correlation with crop response than with half an hour's digestion of the soil before filtering. The latter procedure may attack a larger percentage of the fertilizer residues remaining in the soil in an unaltered form."

From further observations cited, "it is apparent that the form in which phosphorus has been applied must be definitely taken into consideration in the interpretation of phosphorus tests. Perhaps the true condition of phosphorus availability in a soil treated with rock phosphate lies somewhere in between the pictures given by the Universal and the Truog methods. In working with half normal acetic acid extracting solutions brought to different pH levels with the addition of sodium acetate, a sharp break in the solubility of rock phosphate occurs at approximately 4 pH. Above 4.5 the solubility remains practically constant at the very low value indicated by the regular Universal test."

The value of rapid soil testing methods, C. H. SPURWAY (*Canner*, 84 (1937), No. 15, p. 16).—The present values and limitations of chemical testing for soil nutrient deficiencies are very briefly indicated in a note contributed from the Michigan Experiment Station.

Some considerations concerning the practical interpretations of soil test results, C. H. SPURWAY (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 102-106, fig. 1).—The author of this contribution from the Michigan Experiment Station points out that "in order for any system of soil testing to attain its greatest practical value, certain conditions must be satisfied as follows: (1) Standards of coincidence of factors and fertility levels should be established for the various crops under the practical conditions of production. (2) The soil tests should show the coincidence of factors and the fertility level in any soil, and hence indicate how the soil should be treated in order to bring it nearer to the standard required by a certain crop.

"The single factor of soil fertility of immediate importance to the crop grower is the most limiting factor, whatever it may be. The most limiting factor, however, may not be a chemical factor. It may be either an excess or deficiency of water, an unfavorable physical condition of the soil, or an unfavorable climatic condition. The possible occurrence of these limiting factors, however, should always be considered in the practical interpretation of soil test results.

"Chemical soil tests should indicate what the most limiting chemical factors, excesses or deficiencies, may be in the order of their occurrence in the whole coincidence of chemical plant growth factors in a soil. Any other procedure in the use of soil testing methods is open to the criticism that the most limiting factor may be overlooked. Until standards of coincidences and best fertility levels shall have been established for cultivated crops, on the basis of the soil testing system used, soil test results can be interpreted only as indications of excesses or deficiencies. The proof lies in the effects produced on the crop by the soil treatments used to correct the unfavorable soil condition."

The application of rapid chemical tests, E. K. WALRATH (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 86-98, figs. 3).—The author discusses the value of chemical tests for soil needs from the viewpoint of the sale of commercial fertilizers.

"Demand by members for more definite information about their individual soils and fertilizer needs was largely responsible for the use of the rapid chemical tests by the Eastern States Farmers' Exchange. When used to supplement experimental data, extension service recommendations, and the field experience of the staff, these tests remove much of the guesswork from recommendations."

Results of rapid tests applied to soils of known fertilizer treatment, D. M. GOSS and A. L. PRINCE (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 94-101).—The authors report from the New Jersey Experiment Stations that "rapid soil tests have been used not only as an aid in giving fertilizer and lime recommendations to those landowners in the State who desire such information, but also to show the changes taking place, or that have taken place, in the various field and cylinder experiments carried on by this station. Morgan's Universal soil testing system [*E. S. R.*, 73, p. 746], with minor modifications, has been used exclusively."

Slight changes in Morgan's procedure in measuring out samples of the soil extract and in the tests for manganese, for phosphates, for potassium, and for calcium are described. For determining soil reaction a form of glass-electrode apparatus was found most satisfactory.

What rapid tests have shown about Indiana soils, S. D. CONNER (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 52-62, fig. 1).—Of the potassium and phosphate tests in use at the Indiana Experiment Station the author states, in part, that "our test will detect raw rock phosphate entirely too easily. Some investigators get around this by using very weak solvents. We wish to keep the test rapid, however, so we try to dissolve in 1 min. what it takes the crop 6 mo. or more. Our phosphate test tends to run too high on light sandy soils and subsoils. Fortunately it applies very well to about three-fourths of our Indiana soils. We depend on experience to interpret the other one-fourth."

"The potash test appears to have fewer exceptions than the phosphate test. It measures exchangeable potash very well. . . . There is one caution to be followed in judging the potash needs of a soil by any test of a soil sample. That is, how far can the roots of the plants go for potash? Quite often the subsoil potash is very available, and if the plants can root deeply they can get along with very little potash in the surface soil. . . . Subsoil phosphate, unfortunately, is much less available than the subsoil potash."

The author notes in conclusion that "the rapid tests show only one factor in soil productivity. The other factors that go to make up fertility must be measured by other means. They are a very valuable addition to our methods of diagnosing the needs of crops and soils."

Reactions of basic materials in fertilizer mixtures, W. H. ROSS and K. C. BEESON (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 24-32, figs. 4).—The

authors briefly outline the types of reaction occurring in the preparation of physiologically neutral fertilizer mixtures. "These reactions are accompanied by changes in the physical as well as in the chemical properties of the mixture. Thus as a result of chemical reaction a mixture may cake or become sticky, it may become more hygroscopic or even less hygroscopic, its free moisture content may change, the availability of its plant-food content may increase or decrease, and the mixture as a whole may decrease in weight due to the evolution of volatile matter such as carbon dioxide." The chemical and physical effects of ammonia, calcium cyanamide, limestone, dolomite, calcined phosphate, basic slag, and blast furnace slag are individually discussed.

The value of different basic materials and of dolomitic limestone of different degrees of fineness in the production of non-acid-forming fertilizers, J. R. TAYLOR, JR., and W. H. PIERRE (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 15-23, fig. 1).—The results of experiments reported from the West Virginia Experiment Station show, in part, that "the soils which received the fertilizer containing no basic supplement became very acid as a result of the fertilizer treatment. (The Wheeling silt loam soil had an original pH of approximately 5.1 and the Wheeling fine sandy loam of pH 6.1). Even under such acid soil conditions (pH 4.28-5.05), however, colloidal phosphate and high-grade rock phosphate had little or no appreciable effect in neutralizing soil acidity." Slag, quenched or unquenched, and dolomitic limestone were distinctly more effective. It was found also that "the production of calcined phosphate from rock phosphate, by which most of the phosphorus becomes citrate soluble, causes approximately two-thirds of the calcium to become readily reactive in neutralizing soil acidity."

The rate of reactivity of dolomite from various sources and of varying degrees of fineness as determined by chemical methods, H. B. SIEMS and H. C. BARTON (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 10-14).—The authors determined, at 10-min. intervals after adding the acid, the extent of the neutralization of 22 cc of N hydrochloric acid by a 1-g sample of the dolomites from various sources and of several degrees of fineness of grinding.

"The results obtained seem to indicate . . . that although fineness of grinding may be an important factor in determining the rate of reactivity of dolomite, the source from which the dolomite is obtained may be equally important."

Relative value of dolomite and raw phosphate as neutralizers of acid fertilizers as affected by a modified Neubauer cropping.—Preliminary report, H. L. COOK and S. D. CONNER (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 4-9, figs. 4).—This preliminary report states the first results obtained in an investigation carried out at the Indiana Experiment Station. A Miami sandy loam subsoil (Indiana), pH 4.8, and a Norfolk fine sand, pH 5.4, were tested by a method described, in part, as follows:

"Barley, rye, oats, wheat, and corn were grown with various treatments and then a final crop of barley without treatment to measure accumulative effects. The crops were grown in Neubauer dishes with 800 g of soil run in triplicate. . . . A crop was planted very thickly, then removed, and the soil thoroughly leached to imitate heavy rainfall during several months in the field. New fertilizer was added, another crop grown, removed, and the soils leached. After five such treatments, one crop was grown without additional fertilization to get residual effect, then the soil removed and mixed. Analyses were then made on soils from each treatment. Whether this series of treatments would exactly duplicate or not the effects obtained in several years of cropping, fertilization, and weathering in the field is not so important. It was hoped, however, that in the short time allowed for the work it would give similar

results." Soil acidity was determined by each of two methods. The percentage of saturation with bases was determined by electrometric titration of an ammonium acetate solution extract. The pH values were determined in water suspensions and in suspensions in normal potassium chloride solution.

The results obtained with each of the two soils are separately summarized in some detail and with general indications as follows:

"With the exception of the Hopkins acidity on the Miama sandy loam, there was a significant similarity trend of results between various treatments on both soils. On the Norfolk sandy loam the better nitrification may be the reason why the raw rock phosphate showed negative effects by pH and percentage saturation. There was in all cases better nitrification with the fine dolomite, the calcium carbonate, the tricalcium phosphate, and the calcium silicates than with the fertilizer alone, or fertilizer neutralized with raw phosphates." The finely ground dolomite and the ground calcium silicates were the best neutralizers for both soils, the quenched calcium silicate (molten slag poured into water) being slightly better than the raw (cooled and ground) silicate in one of the two cases.

The influence of fertilizer constituents and leaching on the acidity of soil-fertilizer mixtures, L. G. WILLIS and J. R. PILAND (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 33-37).—These authors (North Carolina Experiment Station) state that "the initial acidity of soil-fertilizer mixtures due to 'salt effect' may have serious consequences in the early part of the season. Until this is removed by leaching it imposes an added burden on neutralizing agents, especially in cool soils. The calcium sulfate content of superphosphate contributes a great part of the salt effect. This is eliminated by leaching but probably with the loss of essential nutrient elements from the soil. The calcium sulfate content of fertilizers can probably be reduced without loss of efficiency, producing a fertilizer giving a lesser quantity of acidity to be neutralized and conserving the natural fertility of the soil. Initially the sulfate (SO_4) radical is more acidic than the phosphate (H_2PO_4), but at final equilibrium there is probably little difference between the two.

"Soluble phosphate retards the rate of reaction of dolomitic limestone in the soil.

"The acidity value of ammoniacal and organic nitrogen due to nitrification is very low in acid soils except where the fertilizer is made potentially neutral with material such as dolomitic limestone."

Acid-neutral fertilizers in vegetable crop production in eastern Virginia, J. B. HESTER and H. H. ZIMMERLEY (*Amer. Soc. Agron., Com. Fert. Proc.*, 1 (1935), pp. 38-43, pl. 1, figs. 4).—According to the Virginia Truck Experiment Station, "degree of fineness of limestone is an important factor in a 'dry-mix' fertilizer in effectively maintaining the soil reaction, during the growth of a crop, against the change in reaction of the soil brought about by using physiologically acid salts in the fertilizer mixture. Dolomitic limestone to be effective in this nature should be of at least 100-mesh fineness.

"Dolomitic limestones of different origin show different degrees of activity in the soil, which is also an important factor.

"Neutral salt mixtures are effective in maintaining the soil reaction against a change caused by acid-forming materials in the mixtures."

A greenhouse study of the effects of fine limestone applied in the row with legume seed on acid soils, L. M. GREINER, R. H. WALKER, and P. E. BROWN (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 2, pp. 157-165).—Greenhouse experiments were made at the Iowa Experiment Station on the acid Marshall and Grundy silt loams. Small quantities of fine limestone in the row with sweetclover seed

on Marshall silt loam caused a depression in the early growth of the plants in deep greenhouse pots, but not with alfalfa or sweetclover on Grundy silt loam. Limestone applied in the row did not appear to depress nodule formation. The death rate of seedlings caused by pythiaceus fungi was decreased 8.4 percent for alfalfa, 3.7 for sweetclover, and 8.2 for red clover by applying fine limestone with the seed at planting. Fine limestone so applied on Marshall silt loam stimulated growth of micro-organisms. As indicated by pH determinations, penetration of limestone when applied in the row was evident in soils receiving water from below only.

Sources of nitrate of soda, R. P. BLEDSOE (*Com. Fert.*, 54 (1937), No. 4, p. 31).—The Georgia Experiment Station has found natural (Chilean) sodium nitrate and a commercial sodium nitrate produced from atmospheric nitrogen to be of equal value, within limits of experimental error.

AGRICULTURAL BOTANY

Notes on types of North American grasses, A. CHASE (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 33–35).—These relate to 19 type specimens not located until after the publication of Hitchcock's Manual of the Grasses of the United States (E. S. R., 73, p. 465).

The determination of the internal gases of plant tissues, C. W. CULPEPPER, H. H. MOON, and J. M. LUTZ (*Science*, 84 (1936), No. 2183, pp. 398–400, fig. 1).—A modification of the Orsat gas analysis apparatus is described and figured, details of procedure are outlined, and the results obtained with various fruits are presented and discussed.

Spectrographic method for determining the carbon dioxide exchange between an organism and its surroundings, E. D. MCALISTER (*Plant Physiol.*, 12 (1937), No. 1, pp. 213–215, figs. 2).—"The spectrographic method for the determination of carbon dioxide as here described makes use of the high opacity of CO₂ gas to radiation in one of its fundamental infrared absorption bands." Wheat was the test plant used.

The range indicator method in pH determinations of plant tissues, J. F. STANFIELD (*Ill. State Acad. Sci. Trans.*, 28 (1935), No. 2, pp. 113, 114).—The method was successfully used to determine the pH values of specific tissues within the plant.

A method for growing and for making permanent slides of pollen tubes, A. V. BEATTY (*Stain Technol.*, 12 (1937), No. 1, pp. 13, 14, fig. 1).—Two methods are described for growing, fixing, and staining pollen tubes (*Eschscholzia* and *Papaver* used), which permit ready measurement of the growth rate and offer a rapid procedure for making permanent slides. A 1.5 percent agar solution with added cane sugar is the medium used. Navashin's fixative and saturated aqueous crystal violet stain, among others, gave good results. By regulating the time intervals for fixing, the different stages of nuclear division can be obtained. An airtight chamber is described for use with pollen tubes which explode on contact with air.

Recent advances in microtechnic.—I, Methods of studying the development of the male gametophyte in angiosperms, P. MAHESHWARI and H. D. WULFF (*Stain Technol.*, 12 (1937), No. 2, pp. 61–70).—"Among methods used for a study of nuclear details in the development of pollen grains, the following were found to be very satisfactory: (1) Warming the entire grains in acetocarmine and then clearing with chloral hydrate; (2) making smear preparations stained with crystal-violet-iodine or iron alum hematoxylin. For paraffin sections, a counterstain with dilute alcoholic erythrosin is often very

useful after the usual iron hematoxylin technic. A method of making cultures of pollen tubes on slides coated with thin films of sugar agar is described in detail. The tubes can be fixed by immersing the slide in formol-acetic-alcohol and then stained by any desired schedule. . . . For studying stages in fertilization or gametogenesis, styles should be fixed and sectioned only after a preliminary study with iodine-chloral-hydrate or safranin-anilin-blue or acetocarmine. . . .

"Some other methods that have not been tried by the authors but appear to be valuable are also briefly described." Forty-three literature references are given.

Microtechnique for winter buds, H. P. BELL and V. FACEY (*Canad. Jour. Res.*, 15 (1937), No. 4, Sect. C, pp. 129-134).—"When preparing winter flower-bud material for microscopic examination, unbroken series of sections cannot be obtained by the ordinary methods of dehydrating, imbedding, etc. This is due to the diverse but characteristic structures found in a resting bud. These structures include heavy impervious protective scales, dense mats of hairs between the young leaves, flowers, and bracts, and a delicate embryonic tissue at the tip. A continuous series of sections may be obtained by (1) making use of extremely sharp tungsten needles to remove the more minute scales and bracts, especially those between the embryonic flowers; (2) soaking the material for at least 2 mo. in 70 percent alcohol; (3) using *n*-butyl alcohol instead of absolute alcohol and xylol; (4) keeping the material continuously at low pressures; and (5) using an alcoholic stain. Each of these additional steps helps, but all are necessary for completely satisfactory results. A method by which the special tungsten needles may be made is described. The continuous treatment at low pressures is made possible by using a 2-oz. bottle fitted with a capillary tube and stopcock. The stains which proved most satisfactory were alcoholic solutions of safranin and acid fuchsin."

A practical device for the rapid quantitative determination of plant pigments, W. A. BECK (*Science*, 85 (1937), No. 2206, p. 368).—Light from a 500-w projection lantern was transmitted through a ray filter and through a solution of chlorophyll, xanthophyll, or carotene in an absorption cell to a photoelectric cell. The current produced was measured by a microammeter. The concentration of the solution used could be determined by comparison with values obtained with graded standard solutions.

Studies on bacterial pigmentation.—II. Growth requirements, R. D. RAM (*Zentbl. Bakt. [etc.]*, 2. Abt., 95 (1937), No. 18-20, pp. 379-389).—From this study by the Pennsylvania Experiment Station, it is concluded that bacterial pigmentation is governed by a variety of factors, the presence of one or several of which may be adequate to produce sufficient pigment so that the absence of some other factors will not be noted. The principal essential element is nitrogen, which may be present in forms unavailable to some chromogens. Carbohydrates increase pigmentation (probably by stimulating growth) when added to media containing a suitable nitrogen source and the essential inorganic constituents, but in the absence of the last two they are unable to support pigment production. Organic metallic compounds do not favor pigmentation. The optimum reaction is pH 6.6-8.0.

"The results obtained from this study are illustrative of conflicting results to be obtained when a large group of organisms of diverse characteristics is studied. The factors influencing pigment production in one culture may differ considerably from those affecting it in others. The preceding experiments indicate the most important factors which may influence pigmentation."

Effect of colored cellophane on the production of sun-red color in maize, W. R. SINGLETON (*Science*, 84 (1936), No. 2187, pp. 488, 489).—In this preliminary study by the Connecticut [New Haven] Experiment Station, ear shoots were excluded from light as soon as they appeared and held in this condition until September 15, when they were kept covered with cellophane bags of various colors until October 1. At this time an intense red had developed under the clear wrappings and under all the colored ones except the dark red. The exact wavelengths most effective in inducing production of the red pigment have not yet been determined, but it is evident that red light alone is not responsible.

[Evaporation records] (*Ohio Sta. Bul.* 579 (1937), pp. 38, 39).—Reports are given on evaporation at Wooster in 1936 and its relation to crop yields, and on evaporation in greenhouses, both by J. D. Wilson.

The relation between rate of transpiration and rate of absorption of water in plants, P. J. KRAMER (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 10-15, figs. 6).—Using Livingston auto-irrigator cones in pots in the greenhouse and outdoors, transpiration, as determined periodically throughout the day for green ash, tulip poplar, loblolly pine, black willow, cactus, and sunflower, was found to exceed water absorption during the day and the reverse at night for all the plants tested except *Opuntia*, in which maximum transpiration occurred from 6 to 10 p. m. rather than near midday as in the rest. Absorption lagged behind transpiration about the same in all. At night stomatal closure checked transpiration abruptly, but absorption did not drop off as rapidly since the saturation deficit in the tissues was not immediately satisfied.

Distribution of the velocities of absorption of water in the onion root, H. F. ROSENE (*Plant Physiol.*, 12 (1937), No. 1, pp. 1-19, figs. 5).—A method is described for simultaneous determination of precise quantitative data on the velocities of tap water absorption by different regions of the same intact root under controlled conditions. All regions between the root cap and the bulb absorbed tap water, but at unequal rates. In relatively young roots there was a unidirectional gradient in the distribution of velocities of water absorption, maximum absorption occurring at the base. In relatively older roots there were two pronounced unidirectional gradients with maximum absorption velocities 40-60 mm from the apex. The velocities of water absorption were less in all root regions between the cap and base in any one root when all the sister roots were present. Removal of the latter increased the rates of absorption in all regions of the remaining root. Each root region went through a maximum with respect to age, having the highest velocity rates when 40-60 mm long. With increased age there was a shift of the region of maximum rates toward the apex.

A working bibliography of day-length and artificial illumination as affecting growth of seed plants, supplement, F. RAMALEY (*Colo. Univ. Studies*, 24 (1937), No. 2, pp. 121-126).—This bibliography of photoperiodism and allied topics supplements one already noted (*El. S. R.*, 70, p. 26).

Respiration of green and chlorophyll-deficient types in maize, M. G. GIBNER (*Amer. Jour. Bot.*, 23 (1936), No. 6, pp. 381-385, figs. 7).—Under normal conditions respiratory rates of normal and albino corn seedlings were found practically identical. The effect of unusual treatments is discussed.

Physiological problems involved in seed dormancy, E. H. TOOLE (*Compt. Rend. Assoc. Internat. Etats Semences (Proc. Internat. Seed Testing Assoc.)*, 3 (1936), No. 1, pp. 33-41).—This is a critical review of recent work (with bibliography of 15 titles) on the occurrence of, and methods of breaking, dormancy and on the physiological changes during dormancy, followed by a general discussion of the factors and problems involved in such studies.

Change in activity of enzymes, soluble carbohydrates, and intensity of respiration of rice seeds germinating under water, P. S. ERYGIN (*Plant Physiol.*, 11 (1936), No. 4, pp. 821-832, figs. 3).—"Germination of rice seeds under water is accompanied by greater loss of dry matter and change in properties of colloidal substances than germination on filter paper. In addition, the volume of the seedling itself increases more rapidly on the filter paper than under water. Soluble carbohydrates are found in greater quantities in the dry seeds of lowland varieties than in those of upland varieties. The main forms of soluble carbohydrates in the rice seeds are saccharose and monosaccharides. Maltose is found during certain stages of germination under water. In general, enzyme action is suppressed in seeds germinating under water especially in the case of saccharase and catalase. This begins from the time of swelling of the seed and continues through the germinating period. . . .

"The respiratory quotient for both lowland and upland varieties when germinated on filter paper is approximately the same, but differs markedly in the case of seeds germinated under water. In the latter case the respiratory quotient is always greater than unity."

The stimulation of seedling plants by organic matter, J. R. PILAND and L. G. WILLIS (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 4, pp. 324-331, figs. 5).—In experiments by the North Carolina Experiment Station, organic materials such as gossypol and the decomposition product of filter paper stimulated growth in mustard seedlings. Copper and manganese effects were additive to those of organic matter. Growth was inversely proportional to the percentage of iron in the tops of mustard plants, and those with filter paper treatments had, in general, less total iron than the other two series.

It is concluded that this phenomenon is associated with the oxidation-reduction equilibrium, that the results pertain to an important function of organic matter in soils and of organic ammoniates in fertilizers, and that copper and manganese promote a favorable reaction.

Blooming of potatoes as influenced by pyrethrum dust, E. O. MADER and E. C. UDEY (*Phytopathology*, 27 (1937), No. 1, pp. 112, 113).—In tests of the 1936 season increased blooming occurred on the pyrethrum-treated as compared with the control plats. The mechanism of this reaction has not yet been determined.

Cytological studies of toxicity in meristem cells of roots of *Zea mays*.—I, The effects of the neutral salts, J. K. EDWARDS (*Amer. Jour. Bot.*, 23 (1936), No. 7, pp. 483-489, figs. 13).—The toxic effects of the chlorides of potassium, sodium, magnesium, and calcium were investigated by exposing the roots to various concentrations of the salt solutions, followed by 48 hr. in acid and basic fixatives, sectioning 8 μ in thickness, and staining with iron-alum haematoxylin.

The influence of several benzene derivatives on the roots of *Lupinus albus*, M. CHERYSOSTOM (*Amer. Jour. Bot.*, 23 (1936), No. 7, pp. 461-471, figs. 13).—As a result of tests with four phenols (phenol, cresol, resorcinol, and pyrogallol), three acids (benzoic, salicylic, and gallic), and two amines (aniline and methyl aniline), it is concluded that there is no apparent agreement between toxicity and complexity of structure in these compounds, but there was some indication of a relation of toxicity with temperature in phenol, cresol, aniline, and methyl aniline.

Bibliography of references to the literature on the minor elements and their relation to the science of plant nutrition, compiled by L. G. WILLIS (*New York: Chleean Nitrate Ed. Bur., Inc., 1936, 2. ed., pp. [51]-[336]*).—This edition contains about 1,000 more references and abstracts than the first (E. S. R., 74. p. 615).

The importance of ash elements in the cultivation of excised root tips, W. J. ROBBINS, V. B. WHITE, J. E. McCLARY, and M. BARTLEY (*Natl. Acad. Sci. Proc.*, 22 (1936), No. 11, pp. 636-639).—At the University of Missouri, the addition of agar or "qualitative" filter paper (not ashless) to flasks containing excised corn root tips in a synthetic culture solution was found to increase average root growth over five times. The ash of qualitative filter paper or agar proved equally effective. Ashless filter paper was ineffective. The need for traces of minerals other than those supplied in culture formulas is thus felt to deserve further study.

Selenium bearing vegetation during late Cretaceous time, O. A. BEATH and C. S. GILBERT (*Science*, 84 (1936), No. 2187, pp. 484, 485).—Evidence presented in this contribution by the University of Wyoming is believed to confirm the theory that many of the existing toxic areas in the Rocky Mountain regions have originated by vegetative enrichment of selenium through cycles of growth and decay of highly seleniferous native plants, such as species of *Astragalus*.

Selenium in soils and vegetation associated with rocks of Permian and Triassic age, O. A. BEATH, C. S. GILBERT, and H. F. EPPSON (*Amer. Jour. Bot.*, 24 (1937), No. 2, pp. 96-101, figs. 2).—From analyses of rocks and plants from the southeastern part of Wyoming to the western border, made by the Wyoming Experiment Station, "it is evident that selenium is definitely a primary constituent of stratigraphically equivalent rocks of Permian and Triassic age. With the possible exception of the Woodside formation, selenium occurs in rock successions which are believed to be stratigraphical equivalents by leading authorities."

Growth of the avocado tree in solution culture, A. R. C. HAAS (*Calif. Avocado Assoc. Yearbook*, 1936, pp. 66-69, fig. 1).—In this contribution from the California Citrus Experiment Station a method for growing avocado trees in various culture solutions is presented. It involves continuous aeration, since oxygen is one of the most important elements for this species. Thus far, young trees have been grown successfully by adding boron, manganese, and iron to the common salts used for culture solutions, and by having aluminum present during the period of omission of phosphate. The method is applicable to various physiological studies of the species.

Pectin in avocado leaves, A. R. C. HAAS (*Calif. Avocado Assoc. Yearbook*, 1936, pp. 72-74).—In this study at the California Citrus Experiment Station analyses are presented of the total pectin content in the dry matter of healthy and tipburned avocado leaves and, for comparison, in that of healthy and mottled walnut leaves. Considerable amounts were found.

Seasonal fluctuations in growth rates of excised tomato root tips, P. R. WHITE (*Plant Physiol.*, 12 (1937), No. 1, pp. 183-190, figs. 4).—"The growth rates of a clone of isolated tomato root tips cultivated in vitro and measured at weekly intervals for a period of 3 yr. show a random fluctuation around a mean due to variations in the behavior of the individual cultures. In addition, these growth rates show a cyclic fluctuation correlated with the seasons of the year. Investigation of the effects of light v. darkness showed that seasonal fluctuations in illumination are a negligible factor in producing this cycle. Investigation proved, however, that such cultures are very sensitive to temperature differences and that the observed fluctuations in temperature are sufficient to account for the observed seasonal variations in growth rate. It will probably be necessary to control the room temperature more accurately than has been done in the past if uniform cultures are to be maintained throughout the year."

The bibliography cites 18 references.

The influence of soil moisture and fertilizers on the specific electrical conductivity of tomato plant sap, A. C. FOSTER and H. C. TATMAN (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 35-39, fig. 1).—"A detailed study has been made of the influence of approximately controlled soil moisture and of fertilizers on the response of tomato plants with reference to growth, amounts of water used daily, water requirement or rate of transpiration, and the relation of this response to the specific electrical conductivity of the plant sap. There appears to be a highly significant relation between the fertilizer materials and water in the soil, the amount of water used daily by the plants, and the ultimate water requirement of the plants. Among cultures grown at different soil moisture contents there occurred a positive correlation between the electrical resistance of the plant sap and the soil moisture. Furthermore, sudden increase in soil moisture caused a corresponding increase in the electrical resistance in the sap taken from leaves, green fruit, and ripe fruit of an individual plant. Successively larger amounts of soil nitrates in different cultures were reflected by correspondingly higher electrolytes in the plant sap as indicated by a lower electrical resistance. Potassium sulfate appeared to have a similar influence. However, the different fertilizer treatments used did not influence the electrical resistance of the plant sap as greatly as did the soil moistures employed."

Secondary root hairs, M. E. PINKERTON (*Bot. Gaz.*, 98 (1936), No. 1, pp. 147-158, figs. 8).—In the monocotyledons studied (Commelinaceae and *Philodendron cordatum*, asparagus, and corn), a so-called "persistent" hirsuteness of practically the whole root system was found to exist. The constituent cutinized hairs proved to be of cortical origin, superseding the primary epidermal hairs. It was deemed logical that this condition may be associated with the lack of secondary thickening, but the function was not determined.

Anatomical structure of stems in relation to the production of flowers, O. C. WILTON and R. H. ROBERTS (*Bot. Gaz.*, 98 (1936), No. 1, pp. 45-64, figs. 43).—By this study at the University of Wisconsin it was found that the flowering stems of all the species examined apparently had certain anatomical characteristics in common, regardless of age or of photoperiodic classification, and they are compared with those of nonflowering stems.

The consistent differences in structure, accompanying the changes in character of growth as seen in sections from stems of plants bearing aborting floral buds and of plants producing a second set of flowers following a period of nonreproductive growth, are offered as evidence that the anatomy of the stem is related to the reproductive character of the plant. The fact that stems of disbudded plants have a structure resembling that of a flowering stem appears to indicate that the characteristic structure accompanies, but is not a result of, the production of flowers.

A critique of plant serology.—I, The nature and utilization of phytoserological procedures, K. S. CHESTER (*Quart. Rev. Biol.*, 12 (1937), No. 1, pp. 19-46).—This critical review discusses the preparation of plant antigens and immune sera, precipitation reactions, anaphylactic reactions, lytic reactions, agglutination reactions, acquired resistance to plant pathogens and toxins, and other serological tests with plant antigens.

The proteolytic enzymes of some common molds, J. BERGER, M. J. JOHNSON, and W. H. PETERSON (*Jour. Biol. Chem.*, 117 (1937), No. 2, pp. 429-438, figs. 2).—The proteolytic enzyme content of 30 common molds (mostly species of *Aspergillus* and *Penicillium*) were studied in detail in this investigation by the University of Wisconsin. The proteolytic system was found to consist of at least 1 proteinase and at least 5 peptidases, viz, a dipeptidase, a carboxypolypep-

tidase, an aminopolypeptidase, and 2 enzymes hydrolyzing diglycine and triglycine. The kinetics of amino nitrogen liberation from gelatin and of the hydrolysis of leucylglycine, leucyldiglycine, chloroacetyl-L-tyrosine, and triglycine by mold enzymes were studied. While the hydrolysis of gelatin and leucylglycine was a zero order reaction, that of the other peptides was of first order. The molds contained the different components in greatly varied amounts. The *Aspergilli* were generally higher in enzyme content than the *Penicillia*, but there was wide variation within the same genus. The amounts of the components varied also with the medium and the incubation time. The optimum H-ion concentration for the proteinase of 3 molds acting on gelatin proved to be about pH 7.

Relative potency of reductase in dry, wet, and germinated *Lupinus albus* seeds, D. I. MACHT and H. F. BRYAN (*Amer. Jour. Bot.*, 24 (1937), No. 3, pp. 133, 134).—"Seeds soaked overnight and extracted by the method described . . . yielded the largest quantity of reducing enzymes. . . . Stems and roots are very poor in reducing substances as compared with either seeds or cotyledons."

Clostridium (Bacillus) tetrylium n. sp., a new species of the *Acetobutylicum* group, W. L. OWEN, R. L. MOBLEY, and R. ARROYO (*Zentbl. Bakt. [etc.]*, 2. Abt., 95 (1936), No. 5-8, pp. 131-134).—This contribution by the Louisiana and Puerto Rico College Experiment Stations describes *C. (Bacillus) tetrylium* n. sp. (including methods of isolation and cultivation), and gives the comparative physiological properties as to their industrial interest for the production of solvents.

Physiological studies with the nitrogen-fixing alga, *Nostoc muscorum*, F. E. ALLISON, S. R. HOOVER, and H. J. MORRIS (*Bot. Gaz.*, 98 (1937), No. 3, pp. 433-463, figs. 9).—This paper gives a full description of the organism and detailed results of physiological studies, from which it is concluded that this blue-green alga is of considerable importance in soils and possibly also in fresh ponds and lakes, adding both nitrogen and organic matter to its growth medium. A general discussion of the economic importance of the *Myxophyceae* in soils is given, and a bibliography of 35 titles is included.

Effect of chemical treatment of pea seed on nodulation by *Rhizobium leguminosarum*, K. J. KADOW, L. E. ALLISON, and H. W. ANDERSON (*Illinois Sta. Bul.* 453 (1937), pp. 12, figs. 4).—Nodulation of peas induced by seed inoculation with *R. leguminosarum* was practically prevented by treatment of inoculated seed with Semesan, cuprous oxide, or Vasco 4 (principally zinc oxide), but these chemicals had no noticeable effect on nodulation by bacteria present in the soil. In many cases the reduction in number of nodules by seed treatment appeared to be partially offset by increases in the size of the individual nodules, and a few cases were observed under commercial field conditions where cuprous oxide treatment of inoculated seed did not materially reduce nodulation. No explanation of the latter finding is yet at hand. In these tests the most consistently satisfactory chemical for pea seed treatment under field conditions was cuprous oxide.

It is believed that varieties not needing treatment might better be inoculated without the seed treatment, so that the bacteria may thus become established in the soil. After this, other varieties needing seed treatment may be grown. Limited data and experience indicate that graphite added to inoculated seed before chemical treatment will permit about one-fourth normal nodulation to occur without materially influencing the effect of the treatment on the stand and vigor of the seedlings.

Acid production by the *Escherichia-Aerobacter* group of bacteria as indicated by dissolved metallic iron, A. V. SYROCKI, J. E. FULLER, and R. L. FRANCE

(*Jour. Bact.*, 33 (1937), No. 2, pp. 185-192, fig. 1).—This is a contribution from the Massachusetts Experiment Station.

Formation of sulfide by some sulfur bacteria, R. L. STARKEY (*Jour. Bact.*, 33 (1937), No. 5, pp. 545-571).—Small amounts of sulfide were found by this study at the New Jersey Experiment Stations to be evolved by *Thiobacillus thioparus* and *T. thiooxidans* growing in fluid media. Various heterotrophic bacteria, actinomycetes, and filamentous fungi also evolved sulfide from inorganic media containing elemental sulfur, and some of the actinomycetes and fungi produced sulfide from thiosulfate in strictly mineral media.

"The hydrogenation of sulfur by the sulfur bacteria suggests the presence of active —SH groups in their cells. This reaction appears to have the same significance with the sulfur bacteria as with the heterotrophic micro-organisms.

"It is considered unlikely that elemental sulfur undergoes hydrogenation preceding its entrance into the cells of the sulfur bacteria which oxidize the sulfur to sulfate."

A three-page bibliography is included.

Viability of bacteria in sea water, S. A. WAKSMAN and M. HOTCHKISS (*Jour. Bact.*, 33 (1937), No. 4, pp. 389-400).—This cooperative study was made by the New Jersey Experiment Stations, the Woods Hole Oceanographic Institution, and the New York Medical College and Flower Hospital relative to the survival of an agar-liquefying marine bacterium and a number of common sea water bacteria added to fresh sea water, to sea water sterilized by heat or filtration, and to prepared salt water. Only the fresh sea water exerted a marked destructive effect. It is suggested that the activities of the animal population of the sea (especially the nanoplankton) can explain, at least partly, both the destruction of the bacteria and the stimulation of the processes of organic matter decomposition. The facts presented are used as a basis for explaining the low numbers of bacteria usually found in natural sea water.

A simple method for preserving bacterial cultures by freezing and drying, H. F. SWIFT (*Jour. Bact.*, 33 (1937), No. 4, pp. 411-421, figs. 2).—Bacteria maintained their original cultural, immunological, and biochemical characteristics and their virulence for many years at room temperature when completely dried in a frozen state, provided the cultures so dried were well sealed. Two methods are described for freezing and drying the material.

A method of freeing fungi from bacterial contamination, J. R. RAPER (*Science*, 85 (1937), No. 2205, p. 342, fig. 1).—A glass ring is placed in a Petri dish of agar medium so that its upper edge extends above the agar. The lower edge is raised slightly above the bottom of the dish by glass rests. The fungus to be freed of bacteria is inoculated onto the surface of the agar within the ring. The hyphae grow down through the agar, under the bottom of the ring, and out into the surrounding uncontaminated agar without the bacteria following. Sterile transfers can then be made with ease.

The use of ultra-violet irradiated culture media for securing bacteria-free cultures of Saprolegnia, I. H. BLANK and W. N. TIFFNEY (*Mycologia*, 28 (1936), No. 4, pp. 324-329, fig. 1).—"Bacteria-free cultures of *Saprolegnia* were readily obtained from badly contaminated sources by first growing the organism on an ultraviolet-irradiated medium containing levulose, peptone, and agar. . . . It is thought that this method will be applicable to the isolation of other fungi."

A note on the temperature relations of certain fungi, N. E. STEVENS (*Mycologia*, 28 (1936), No. 6, pp. 510-513, fig. 1).—Using species of *Diplodia*, *Physalospora*, and *Botryosphaeria* grown on agar plates in an unusually accurate series of temperature chambers, the radial growths in 24-hr. periods were determined and are presented graphically.

Continued study of these fungi led to the conviction that the spore size and the growth rate are, in some way not yet understood, related in a significant manner, the larger spored fungi apparently being much less common and widely distributed in nature and their growth rates much slower.

GENETICS

An improved method for the study of chromosomes, E. C. JEFFREY (*Stain Technol.*, 12 (1937), No. 1, pp. 9-12).—Using the chromosome fixation method described, excellent results were obtained by cutting up the material in very thin slices of almost microscopical tenuity and passing them immediately into fixing solutions containing osmic acid. The material was then assembled on cards, and, after embedding in nitrocellulose, sectioned to 5μ or even thinner. Practically all methods of staining may be used, but best results were obtained with Heidenhain's hematoxylin bleached almost to disappearance and followed by prolonged treatment with aqueous safranin. The differentiation of the chromosomes thus obtained indicates that they consist of a ground substance in which are situated two chromatids. In somatic tissues these chromatids generally appear to be spirals running in opposite directions. The crossing points of these spirals are responsible for the optical illusion which has been designated the "gene."

Symbols for genes [trans. title], H. NACHTSHEIM, R. SCHICK, and O. VON VERSCHUER (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 73 (1937), No. 1, pp. 55-62).—Suggestions are given for a nomenclature which might be internationally adopted for genes.

Studies on the genetics of smuts of barley and oats in relation to pathogenicity, C. C. ALLISON (*Minnesota Sta. Tech. Bul.* 119 (1937), pp. 34, figs. 9).—In Minnesota loose smut (*Ustilago nuda*) is more prevalent than covered smut (*U. hordei*), probably due largely to relative differences in the susceptibility of the barley varieties commonly grown and to differences in the effectiveness of seed treatments for the two smuts.

For study of the pathogenicity and genetics of *U. hordei* and *U. medians*, the partial vacuum method of barley seed inoculation with chlamydospores gave much better infection than the dusting method and also proved most satisfactory for inoculating barley or oat seeds with monosporidial combinations. Collections of *U. hordei* were found to differ from one another in virulence for 11 barley varieties, and 27 of 28 collections could be differentiated on 6 of these varieties. On the basis of type of smutted plant produced, 3 collections could be further differentiated on Minnesota No. 474 grown in the greenhouse.

Factors for sex in *U. hordei* and *U. medians* segregated in a 2:2 ratio, and factors for cultural characters in *U. hordei* segregated in ratios of 3:1, 2:2, and 0:4, and independently of the factors for sex. Variants differing culturally from the parent colonies were observed. *U. hordei* hybridized readily with *U. medians*, as shown by sporidial fusions and production of viable chlamydospores. Chlamydospores in F_1 were echinulate, and the smutted head type was intermediate. The F_2 segregated for chlamydospore wall character and for head type, although there appeared to be no linkage. Combinations of head type and chlamydospore wall markings differing from either parent type occurred in F_2 . Segregation for pathogenicity occurred in F_2 dicaryophytes, and some of the latter were more pathogenic for certain varieties than the parent dicaryophytes. *U. hordei* and *U. medians* hybridized with *U. avenae*, *U. levis*, and *U. tritici* as far as fusions and initiation of the dicaryophase, but

seed inoculations with these combinations failed to produce smutted heads and no smut hyphae were found in the young seedlings. The meager data on hybridization of *U. hordei* and *U. medians* \times *U. nuda* were negative for production of smut mycelia or chlamydospores in the hosts. The nuclear condition of the sporidial fusions apparently differed but little in intra- and interspecific crosses. The dicaryophase was initiated soon after fusion when the two nuclei of a fusion pair became associated in the same sporidium.

When the chlamydospores of *U. hordei* germinated beneath the seed hull they typically produced a promycelium, the cells of which readily fused instead of producing sporidia. The nuclear condition of these fused promycelial cells was evidently similar to that of fused sporidia. The *U. hordei* mycelium was predominantly dicaryotic in the host, but many hyphae with one or more than two nuclei per cell were observed.

Genetical studies on mutants in the progeny of heat-treated barley, F. H. PERO (*Canad. Jour. Res.*, 15 (1937), No. 5, Sect. C, pp. 217-229, pl. 1).—After heat treatments were applied to barley seeds, different mutant characters observed in the progeny included xantha_{1,2}, dwarf_{1,2,3,4}, virescent_{1,2}, chlorina, and albino. While typical Mendelian ratios were not obtained in the first segregating generation, owing to the small size of the sector affected in the generation of treatment, in the second and third segregating generations good fits were obtained in all cases to either monohybrid or dihybrid ratios. Both 3:1 and 15:1 ratios were observed in lines segregating for xantha₁ and albino characters, requiring the postulation of the duplicate factor hypothesis to explain this situation. Chlorina and dwarf mutants segregated in all the cases investigated as simple Mendelian recessives. One virescent strain, believed to have arisen through plastid mutation, was maternally inherited. The heat treatment increased significantly the natural mutation rate for the xantha characters, but apparently had no effect on the albino mutation rate. Dwarf, virescent, and chlorina mutants were observed in the segregating generation after heat treatment, but were not detected in untreated populations.

Inheritance in barley, II, D. W. ROBERTSON (*Genetics*, 22 (1937), No. 4, pp. 445-451).—The second in this series (E. S. R., 69, p. 344) reports tests of three chlorophyll-deficient seedling factor pairs with known factor pairs located in the seven different linkage groups in barley.

A factor pair *A₂₃a₂₃* for green v. white seedlings in Coast II was found linked with *N_n* (covered v. naked seeds) in group III, with 27.24 ± 2.04 percent crossing-over. *A₂₃a₂₃* was inherited independently of factor pairs located in five of the other linkage groups. *X₂x₂* (green v. yellow seedlings) in Smyrna I (citron green of Ridgway) was found linked with factor pairs found in group VI. *A₇a₇* (green v. white seedlings) found in *Hordeum distichon nigrinudum* I was found linked with *X₂x₂* and a factor pair in group VI. The linkage relations with percentages of crossing-over were *A₂₃a₂₃* and *X₂x₂* linked with less than 4 percent of crossing-over (E. S. R., 60, p. 726), *X₂x₂* with *A₂₃a₂₃* with 25.74 ± 1.73 percent, *A₇a₇* with *X₂x₂* with 9.87 ± 0.65 percent, and *X₂x₂* linked with *A₇a₇* with 15.49 ± 0.86 percent. The linear arrangement evidently is *A₂₃a₂₃*, *X₂x₂*, *A₇a₇*, and *X₂x₂*. Indications were that *A₇a₇* and *X₂x₂* are inherited independently of factor pairs located in the other linkage groups.

Failure of diakinesis and metaphase pairing and the behavior during meiosis of univalent chromosomes in Zea mays, L. R. POWERS and A. O. DAHL (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 9, pp. 655-668, pls. 4).—In a cytological study at the Minnesota Experiment Station involving progeny of inbred lines of corn, H93 and H94, the variance of data taken on the

proportion of bivalents to univalents for diakinesis was 3.6 times that of the binomial distribution. For meiocytes possessing only two univalents, the distribution of chromosomes during anaphase I was entirely random for univalent chromosomes, and hence the probability of the members of any one set of univalent and homologous chromosomes going to opposite poles was 0.5. A positive association was found between degree of failure of pairing during diakinesis and metaphase I (apparently affected by the environment) and chromatin loss.

The behavior of the extra univalent chromosome during meiosis differed from the normal complement in that it always preceded the members of the bivalent complements to the poles and was not lost in either division I or II. It was evident that this extra chromosome is not composed completely of inert material, but carries at least one gene.

The crossing plot for increasing inbred corn seed, W. R. SINGLETON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 81-83).—Practical suggestions derived from genetic work with corn at the Connecticut [New Haven] Experiment Station are reported.

On the occurrence of "crinkled dwarf" in *Gossypium hirsutum* L., J. B. HUTCHINSON and R. L. M. GHOSE (*Jour. Genet.*, 34 (1937), No. 3, pp. 437-446, pls. 2).—A crinkled dwarf in Indore 1 cotton (*G. hirsutum*) arose as a mutant at the same locus as crinkled dwarf in *G. barbadense*, and behaved as a complete recessive in crosses with normal strains of Upland. In an F_2 of a cross between Indore crinkled and the Egyptian wrinkled leaf (identical with Sea Island crinkled dwarf), all grades between fully normal and extreme crinkled were obtained, an exactly parallel behavior to that found by Harland (El. S. R., 74, p. 181) in crosses between Sea Island crinkled and crinkled transferred to the Upland genotype. The bearing of the data on Fisher's theory of the origin of dominance by selection among heterozygotes is discussed.

A cytological study of the genus *Poa* L., J. M. ARMSTRONG (*Canad. Jour. Res.*, 15 (1937), No. 6, Sect. C, pp. 281-297, figs. 31).—In determinations of the somatic chromosome numbers of 20 species of *Poa*, made at the Dominion Experimental Farms, Ottawa, the basic chromosome number for the genus was found to be 7. The species arranged themselves in a polyploid series from diploid to dodecaploid, tetraploids and hexaploids being the most numerous. Three aneuploid species possessed chromosome numbers suggestive of a non-aploid origin. Polymorphism was found in *P. compressa*, *P. palustris*, and *P. nemoralis*. All species examined conformed to the long chromosome type common to the subfamily Pooideae. The spindle fiber attachment for the chromosomes in the various species ideograms was found to be regularly median or submedian.

The chromosome variability and mode of seed production were examined in *P. pratensis*, using selected, uniform strains, indigenous plants, and plants from commercial seed. The somatic chromosome number was found to range from 50 to 87 ± 1 , 10 of 19 plants examined possessing aneuploid numbers. The selected strains possessed the same chromosome number for both plants examined, while in the other material the number varied. A study of meiosis in the pollen mother cell showed the selected strains to vary from regular behavior to an irregularity of 3.9 unpaired univalents per cell. All strains had large percentages of morphologically good pollen which germinated actively on the stigmas. Reduction was observed in the egg mother cell of the selected strains, and a study of the course of embryological development showed no irregularities which might lead to aposporous reproduction. A high frequency of polyembryony observed was correlated to the degree of irregularity at

meiosis. A theory is advanced to explain how constant aneuploid numbers may be maintained in sexually reproduced strains.

Cytological and embryological investigation of potatoes in connection with their sterility, R. A. BELLIS (BAYLISS) (*Zhur. Inst. Bot. Ukrain. Akad. Nauk (Jour. Inst. Bot. Acad. Sci. Ukraine*, 10 (1936), No. 18, pp. 99-143, figs. 75; *Eng. abs.*, pp. 128-130).—From a detailed study involving 17 potato varieties (1933-34), it is concluded that the basic cause of sterility evidently lies in abnormalities of meiosis in the pollen mother cells, which arise from the unbalancing of the chromosomes—possibly because of the hybrid origin of the potato. In different varieties this unbalancing is manifested unequally, which appears to condition the different degrees of fertility in individual varieties. Environmental conditions are also considered important factors in sterility, but the observation of the same abnormalities in male gametophyte development by investigators in different continents and latitudes and under different climatic conditions suggests that the basic cause lies in internal rather than in external conditions.

Methods of strawberry breeding in Louisiana, J. C. MILLER (*Amer. Soc. Hort. Sci. Proc.*, 33 (1936), pp. 339, 340).—Assembling varieties known to possess some degree of resistance to leaf spot (*Mycosphaerella fragariae*) and scorch (*Diplocarpon earliana*), crosses were made at the Louisiana Experiment Station in an attempt to develop new strawberries sweeter than Klondike but retaining the firmness and other desirable characters of that variety. Crosses were made in April or May, seeds held in cold storage until the next February when sown in flats, the plants were set out of doors on about June 1, and the seedlings were sprayed repeatedly with spore suspensions of the above two organisms. On a basis of disease resistance and of desirable quality, only about 2-5 percent of the seedlings were saved for the second year's observations.

Breeding hardy grapes, A. F. YEAGER (*Amer. Soc. Hort. Proc.*, 33 (1936), pp. 414, 415).—Stating that *Vitis vulpina* withstands North Dakota winters without injury, the author reports on breeding work at the North Dakota Experiment Station in which an F₁ generation was produced from *V. vulpina* × Concord and *V. vulpina* × Eclipse. Of the 139 seedlings which survived the cold winter of 1935-36, 67 fruited in 1936, bearing white or purple fruit ranging in size from *V. vulpina* to Eclipse and in flavor from very acid to sweet. Failures to obtain segregates in selfing Beta and Alpha varieties are believed to indicate that these are not hybrids but probably simply *V. vulpina* or some botanical variety thereof.

Hybridization studies on a zinc-induced variant of *Hypomyces ipomoeae*, A. W. DIMOCK (*Mycologia*, 29 (1937), No. 3, pp. 273-285, figs. 2).—A striking variant was produced in experiments by the University of California through cultivation of monoploid hyphae of *H. ipomoeae* on a medium containing a sublethal dosage of zinc nitrate, but the genic alteration or mutation cannot be considered a specific effect of the zinc ion without further evidence.

The effect of phosphorus on chromosome and nuclear volume in a violet species, W. P. PIERCE (*Bul. Torrey Bot. Club*, 64 (1937), No. 6, pp. 345-355, pl. 1, figs. 2).—The results of this study by the Vermont Experiment Station indicated an increase in chromosome volume induced by an excess of phosphorus. The relations of the findings to plant size and vigor are discussed.

Progeny tests of dairy sires, G. BONNIE (*Hereditas*, 22 (1936), No. 1-2, pp. 145-166).—A comparison of several bull indices showed that the index of least variance is the best for recalculating the data for each year, but for prediction purposes an index based on dam-daughter comparisons seemed most serviceable.

Impacted molars: A new lethal in cattle, E. E. HENNER and M. C. HENNER (*Jour. Heredity*, 28 (1937), No. 3, pp. 123-128, figs. 4).—A condition of impacted

molars resulting in a parrot-mouthed appearance was found in eight calves born in an inbred Milking Shorthorn herd. The abnormal calves died during the first week. Pedigrees of five calves which could be traced indicated that the condition was due to the action of a single pair of recessive genes. The occurrence of lethal factors in cattle is reviewed.

Albinism in a cocker spaniel, J. McI. PHILLIPS (*Jour. Heredity*, 28 (1937), No. 3, pp. 103, 104, fig. 1).—The production of a pure white male in a litter with five red and white males by red and white cocker spaniel parents is noted. The puppy had blue eyes without deformity. There were a few light brown flecks in the skin of the nose, lips, and footpads.

A "cat-dog" from North Carolina: Hairless gene or "maternal impression"? H. STERNBERGER (*Jour. Heredity*, 28 (1937), No. 3, pp. 115, 116, fig. 1).—The occurrence of a hairless kitten with a short tail and some dog-like habits in a litter with four kittens, two others of which also had short tails, is noted.

The antiquity of mouse variations in the Orient, C. E. KEELER and S. FUJII (*Jour. Heredity*, 28 (1937), No. 3, pp. 93-96, figs. 3).—Oriental art objects from the eighteenth century depict characteristics of albino, pink-eyed dilute, chocolate, black-eyed white, recessive piebald, black, white face, and possibly waltzing mice.

The inheritance and expression of fused, a new mutation in the house mouse, S. C. REED (*Genetics*, 22 (1937), No. 1, pp. 1-13).—An account is given of the genetics of a character in the house mouse designated as "fused", which varies in its expression from asymmetrical fusion of vertebrae, the lack of all or part of the tail, or fusion of ribs at the proximal ends to normal. The fused gene is dominant to the normal except for normal overlaps in both homozygous and heterozygous animals and is linked with brachyury. Selection for modifying factors by breeding with strongly fused in one line and weakly fused animals in another was ineffective. In reciprocal backcrosses of F_1 s (fused) to normals significantly different percentages of normal and fused progeny were obtained, suggesting the operation of extrachromosomal influences on the expression of the fused gene or the action of modifying factors contributed by certain strains. Evidently the *Mus bactrianus* species carried modifying factors preventing the expression of fused. In crossing fused mice with this species, the F_1 and backcross to normal progeny were normal. Bifurcated tails were frequently observed in fused animals, but the variation in the fused condition did not seem to be hereditary. Tests were made of the linkage relations between the fused gene and the 12 linkage groups with negative results. However, there was such a close linkage (less than 10 percent crossing over) between fused and brachyury that an allelic relationship was suggested.

Studies on spotting patterns, I-III (*Genetics*, 22 (1937), Nos. 1, pp. 14-64, figs. 4; 2, pp. 307-318).—Three papers are reported.

I. Analysis of quantitative variations in the pied spotting of the house mouse, L. C. DUNN and D. R. CHARLES (pp. 14-42).—Quantitative determination was made of the percentage of white and black on the dorsal and ventral surfaces of pied *ss* mice. Through inbreeding and selection in *ss* individuals, belted, white-faced, and all-white lines were produced which showed much less variability as regards the amount of white exhibited by any one line. Specific strains breeding relatively true were also developed within these lines for such characters as width of belt and location of spots. The variations which existed after more than 20 generations of inbreeding were considered to be mainly nongenetic, since about the same type of progeny was produced by the parents exhibiting the variations. Further it was impossible to fix these variations. In crosses between the purified strains, the F_1 s and F_2 s were

intermediate between the parents with greater variation in the F_2 s. By crossing spotted strains together, the results indicated the operation of a gene complex designated as K and consisting of at least three genes modifying the dominance of S over s and the relative amounts of spotting produced. In the absence of the spotting gene the factors in the modifier complex may themselves cause spotting.

II. *Genetic analysis of variegated spotting in the house mouse*, L. C. Dunn (pp. 43-64).—In making a genetic analysis of the variations in pattern of variegated mice and the interaction with the other spotting genes, it was found that variegated mice produced several kinds of progeny in addition to variegated, i. e., anemic young which died soon after birth, self-colored, black-eyed white, and pied offspring. All were nonagouti black $aaBB$ and heterozygous for W in combination with S or s . There was much variation from the black-eyed whites to those with only a few white hairs. Fourteen generations of selection for increased amounts of white spotting in $WicSS$ variegated mice showed the effects of a combination of at least three modifying factors for white spotting acting mainly on W . The $WicSS$ individuals were 90 to 93 percent white, and the $wicSS$ individuals showed a maximum of 5 percent white as a result of the combined action of these modifiers designated as $m(W)$. The anemics (WW) were black-eyed white. Quantitative variations in the amounts of black and white in the variegated pattern were due to these modifiers and nongenetic causes. These studies showed that W acts as a dominant when the complex of modifiers is present and as a recessive in the presence of the alleles of these modifying factors, regardless of the spotting genes. With intermediate numbers of the modifying genes, W is incompletely dominant.

III. *Interaction between genes affecting white spotting and those affecting color in the house mouse*, L. C. Dunn, E. C. MacDowell, and G. A. Lebedeff (pp. 307-318).—Continuing this series, measurement was made of the white areas on the yellow pied and black pied progeny produced by crossing yellow pied (A^yass) and black pied ($aass$) mice. The measurements showed the yellow pied individuals to be 61.85 ± 0.74 percent white and the black pied 72.05 ± 0.65 percent white. Likewise, the yellow progeny from crossing yellow black-eyed-whites ($A^yawicss$) with black peds showed the presence of smaller areas of white than their black litter mates. To be assured that this reaction was between the genes for yellow and white spotting and not due to modifiers of W , the $m(W)$ genes, the amount of white was determined on the yellows and blacks produced by backcrossing yellow hybrids from a yellow self ($A^yAwicSS$) \times a black light variegated line ($aaWicSS$) + $m(W)$ to the black variegated line. The amount of spotting on the yellows was again less than that on the blacks. Since the amount of spotting in the variegated pattern is determined by specific modifiers of W , the yellow gene must interfere with the action of $m(W)$. Further results showed that the yellow gene had no important effect on spotting due to the s and k genes.

The transmission of breast and lung cancer in mice, J. J. BITTNER and C. C. LITTLE (*Jour. Heredity*, 28 (1937), No. 3, pp. 117-121).—The incidence of mammary carcinoma in reciprocal crosses between high and low tumor lines showed such wide differences in accord with the incidence in the strain from which the mother was derived that extrachromosomal forces were postulated. The breast cancer-producing influence was apparently transmitted through the milk of the high breast cancer stock females. Modifications in the incidence were brought about by fostering young on mothers from other stocks. Lung tumor incidence seems due to the action of one or more dominant factors with nonsignificant differences in reciprocal crosses.

Investigations on silver and red foxes based on the phenotypic characteristics of the pelt [trans. title], C. HOLECEK-HOLLESCHOWITZ (*Ztschr. Zücht., Reihe B, Tierzucht. u. Züchtungsbiol.*, 37 (1937), No. 1, pp. 37-76, figs. 32).—Study was made of the phenotypic variations in the hair and colors of 500 fox pelts.

Genetics of the fowl.—VI, A tentative chromosome map, F. B. HUTT (In *Neue Forschungen in Tierzucht und Abstammungslehre* [Duerst Festschrift]. Bern: Verbandsdruckerei AG., 1936, pp. 105-112, fig. 1).—Continuing this series (E. S. R., 76, p. 319), the location of genes for head spot, inhibitor of dermal melanin, barring, brown iris, light down, silver and slow feathering in the sex chromosome; crest, dominant white and frizzling; creeper, rose comb and uropygial; silkie and flightless; and pea comb, marbling in down, and naked neck in other groups are postulated with a presentation of a map for these five chromosomes in the fowl.

Developmental analysis in plumage.—I, The individual feather: Methods, M. JUHN and R. M. FRAPS; II, Plumage configurations and the mechanism of feather development, R. M. FRAPS and M. JUHN; III, Field functions in the breast tracts, R. M. FRAPS and M. JUHN (*Physiol. Zool.*, 9 (1936), No. 3, pp. 293-318, pls. 2, figs. 6; pp. 319-377, pls. 5, figs. 19; pp. 378-406, pl. 1, figs. 8).—These papers deal with the development of the individual feather, involving measurements of pattern components in the definitive mechanism of feather growth, accounting for certain patterns and the asymmetry and gradient relations of the breast tracts.

The inheritance of shank color in chickens, P. D. STURKIE, C. B. GODFREY, and R. M. SHERWOOD (*Poultry Sci.*, 16 (1937), No. 3, pp. 183-188).—In studies at the Texas Experiment Station, crosses were made of White Leghorn, White Orpington, and Brown Leghorn hens with Black Langshan roosters to determine the inheritance of color. In explaining the results it is suggested that the sex-linked gene *D* for shank color produces predominantly light shanks and is independent of the inhibitor *I*, color *C*, and extension *E* genes. The action of the *D* gene is delayed until about 2 mo. of age. In combination with the gene for extension of melanic pigment, *d* birds may vary in shank color with variability in heterozygous (*Ee*) individuals from black to blue. In combination of recessive *e* and dominant *D*, the shanks are perfectly white or yellow. The action of the extension factor on the shanks and down of chicks is inhibited by the gene *I*. The barring gene *B* almost completely inhibits melanic shank color.

The inheritance of egg production in the domestic fowl, I-IV (*Sci. Agr.*, 16 (1936), No. 11, pp. 591-607, figs. 4, Fr. abs., p. 607; 17 (1937), No. 6, pp. 376-400, figs. 2, Fr. abs., pp. 385, 392, 400).—Four papers are given.

I. General considerations, S. S. Munro (pp. 591-607).—General considerations regarding the inheritance of egg production and the influence of gene-gene and gene-environment interactions with methods of measuring the variability in Mendelian populations are presented. The necessary effort involved in phenotypic selection is not considered warranted by the results that may be expected.

II. Increases in production, their extent and characteristics, with a discussion of causal factors, S. S. Munro (pp. 376-385).—A statistical analysis of the production records of Barred Plymouth Rocks from 1920 to 1935 showed that the mean increased in succeeding years but the standard deviation was practically unchanged, although there was some skewness in the distribution of the production in later years. The increases in production which have occurred are considered to be due, in the main, to nongenetic causes.

III. *Differences in transmitting ability of dams, and the degree of dam-daughter correlation*, S. S. Munro, S. Bird, and J. W. Hopkins (pp. 386-392).—An analysis of the variance in the egg production of 1,165 Barred Plymouth Rock pullets from seven Dominion experimental farms when grouped by sire and dam showed that there were considerable differences in the production of daughters from the same sire from different dams. As the significance could not be shown in the smaller groups, it is considered that the genetic differences played a relatively small part in determining the total variations. The correlation between the production of all dams and daughters of 0.152, although statistically significant, was so small as to be of little practical importance in the selection of dams on the basis of their production.

IV. *Reliability of progeny tests of sires*, J. W. Hopkins, S. S. Munro, and S. Bird (pp. 393-400).—The egg records of the Barred Plymouth Rock pullets in the above studies were analyzed to determine the variance in the production of full and half sisters and the proportion of the variance which was due to environmental conditions, locality, and season. The numbers of eggs that must be laid by different numbers of dams and daughters in excess of a set standard for a 5-percent level of significance under the same and different environmental conditions are tabulated.

Investigation of the inheritance of blood group antigens in fowls, II [trans. title], O. THOMSEN (*Hereditas*, 22 (1936), No. 1-2, pp. 129-144).—Further study of this problem (E. S. R., 72, p. 603) is reported, based on intermixtures of blood from the parents and the progeny with data on the agglutinations.

A technic for the sectioning of mammalian ova and blastocysts, W. W. GREEN, C. BARRETT, and L. M. WINTERS (*Stain Technol.*, 12 (1937), No. 2, pp. 43-47, fig. 1).—Descriptions are given for fixing, sectioning and staining mammalian ova and blastocysts.

[Modification of mammalian sexual cycles.—IV.] Relations of hair cycles in ferrets to changes in the anterior hypophysis and to light cycles, T. H. BISSENETTE (*Anat. Rec.*, 63 (1935), No. 2, pp. 159-168).—This continuation of the series (E. S. R., 74, p. 327) demonstrates the relationship between the hypophysis, sexual cycles, and hair cycles and light in the ferret.

Modification of mammalian sexual cycles.—V, The avenue of reception of sexually stimulating light, T. H. BISSENETTE (*Jour. Compar. Psychol.*, 22 (1936), No. 1, pp. 93-103).—Continuing the series above noted, the eyes are indicated as the receptors for photoperiodic stimulation in ferrets through investigations in which the animals were hooded, with and without eyeholes. Oestrus was significantly delayed in animals completely hooded and not in others.

Modification of mammalian sexual cycles.—VI, Litters from ferrets in January induced by increased exposures to light after nightfall, T. H. BISSENETTE and E. E. BAILEY (*Amer. Nat.*, 70 (1936), No. 730, pp. 454-458).—In continuation of the series noted above, it is suggested that frequent copulation within a few hours may cause luteinization of ovarian follicles without ovulation in the ferret. Consequently, only one mating was permitted in these tests. A male and three females were brought into sexual activity by graduated exposure to electric light after nightfall. Two females became pregnant and one had a litter, although the young were unable to survive.

Modification of mammalian sexual cycles.—VII, Fertile matings of raccoons in December instead of February induced by increasing daily periods of light, T. H. BISSENETTE and A. G. CSEGEH (*Roy. Soc. [London] Proc., Ser. B*, 122 (1937), No. 827, pp. 246-254).—Continuing the above series, three pens of one

male and two female raccoons each at the Shade Swamp Sanctuary, Farmington, Conn., were lighted at night from October 10 through the rest of the season for intervals ranging from 1 to 8 hr. These animals mated in December, as contrasted with the controls, which first mated in February. Three of the females artificially lighted successfully reared young in spite of the subzero weather. Two of the three females in the lighted pens mated again in May but did not produce second litters.

The artificial induction of oestrus in the goat during anoestrus, T. S. SUTTON and W. R. KRELL (*Ohio Sta. Bul.* 579 (1937), p. 81).—Oestrus was induced in goats during the anoestrous period by the administration of gonadotropic substance from anterior pituitary extracts. The gonadotropic substances of human pregnancy urine and the anterior pituitary evidently differ.

Biological investigations of the spermatozoa of bulls, W. BRETSCHNEIDER (*Biologische Untersuchungen an den Samenzellen des Bullen. Inaug. Diss., Univ. Leipzig*, 1936, pp. 44).—Results are reported on the duration of motility of spermatozoa of bulls as influenced by testicular extracts and other substances.

Hypophysectomy and replacement therapy in relation to the growth and secretory activity of the mammary gland, E. T. GOMEZ and C. W. TURNER (*Missouri Sta. Res. Bul.* 259 (1937), pp. 72, figs. 17).—Results of numerous experiments dealing with the influence of hypophyseal secretions on mammary gland activity in laboratory animals showed, in general, that the administration of ovarian hormones, estrogen, and progesterin, with desiccated whole sheep pituitaries, alone and in combination, failed to stimulate growth of the duct system of the mammary gland of hypophysectomized laboratory animals. Daily implants for from 20 to 25 days of rat pituitaries from donors previously injected with estrogen daily for from 10 to 20 days stimulated proliferation of the lobule-alveolar system of the mammary glands of normal and castrated hypophysectomized male and female guinea pigs, indicating that growth of the mammary gland is under the direct influence of one or more specific hormones of the pituitary produced only after stimulation by the ovarian hormones.

Hypophysectomy during lactation resulted in the cessation of milk secretion. The simultaneous injection of galactin, glucose solution, and the adrenotropic hormone or adrenal extract was capable of initiating or stimulating lactation in hypophysectomized guinea pigs and rabbits.

The pituitary glands of ewes in various phases of reproduction, V. WARBURTON and F. F. MCKENZIE (*Missouri Sta. Res. Bul.* 257 (1937), pp. 59, figs. 28).—Cytological study was made of the pituitaries from 60 ewes slaughtered in different phases of the reproductive cycle. Four portions of the pituitary, glandular, neural, intermediate, and tuberal, and nine different cell types were identified. It was suggested that both granular and nongranular cell types were instrumental in the production of a follicle-stimulating substance and possibly of a lactogenic substance. Granular cells were thought to produce a luteinizing and possibly a mammatropic substance required for the growth of the mammary gland during the last half of the gestation period. A scheme is suggested to account for most of the observed phenomena of reproduction and the pituitary changes accompanying them.

The type and degree of gonadal stimulation induced in hypophysectomized male rats parabiotically joined with castrated, cryptorchid, and normal partners, EUGENE CUTULY, D. R. MCCULLAGH, and ELIZABETH CUTULY (*Endocrinology*, 21 (1937), No. 2, pp. 241-248, figs. 16).—Greater stimulation of the testes occurred in hypophysectomized male rats joined in parabiotic union

with castrates than when the union was with normal or cryptorchid partners, suggesting a greater production or liberation of gonad-stimulating hormone from the hypophysis of castrated than from the normal animals. Both the germinal and interstitial tissues were equally stimulated, tending to support the hypothesis that only one rather than two gonadotropic hormones from the hypophysis is required to stimulate normal functioning of the testes.

The interrelationship of the pituitary sex hormones in ovulation, corpus luteum formation, and corpus luteum secretion in the hypophysectomized rabbit, M. A. FOSTER, R. C. FOSTER, and F. L. HISAW (*Endocrinology*, 21 (1937), No. 2, pp. 249-259, figs. 15).—Hypophysectomy of female nonpregnant rabbits resulted in diuresis and blanching of the vulva on the first day, followed by atresia of the large follicles. The administration of 2 to 3 rat units daily of follicle-stimulating hormones begun 2 or 3 days after hypophysectomy prevented the follicular atresia and atrophy of the uterus which usually follows hypophysectomy. If the follicle-stimulating hormone was delayed until later, and if antra-containing follicles were still present, there was an increased oestrin output with constant oestrus production. In the hypophysectomized rabbit, ovulation could be induced by administering follicle-stimulating hormone from the horse or hog pituitary for 5 days to stimulate follicular growth and following this in 8 to 10 hr. by an intravenous injection of a mixture of 50 parts follicle-stimulating to 1 part luteinizing hormones. Ovulation followed in 18 to 24 hr., but could not be induced a second time in the same animal or later than 23 days after hypophysectomy. Functional corpora lutea developed after ovulation only in cases where additional lutein hormone was administered.

Some responses of the immature female fowl to injections of mare gonadotropic hormone and oestrin, V. S. ASMUNDSON, C. A. GUNN, and A. A. KLOSE (*Poultry Sci.*, 16 (1937), No. 3, pp. 194-206, figs. 11).—In studies at the California Experiment Station, the response of crossbred Rhode Island Red, Barred Plymouth Rock, and White Leghorn chickens to injections of pregnant mare serum and oestrin prepared from pregnant mare urine is described. The periods of injection ranged from 5 to 42 days. The general effects on external appearance, weight, and size of the ovaries and oviducts showed that the combs of the Leghorns responded more quickly than the combs of the crossbreds. The ovaries of young crossbred chicks were enlarged from injections of pregnant mare serum through an increase in the interstitial tissue without apparent effect on the follicles. The ovaries of the older birds were similarly enlarged but were also hyperemic, although less response was noted than in younger birds. Changes in the oviducts, bursa, and long bones are described and assumed to be caused by the secretory activity of the ovary.

On the synthesis of the female ovarian hormone "Folliculosterone", I. A. REMEZOV (REMISOV) (*Biokhimiia*, 2 (1937), No. 2, pp. 344-366, figs. 7; *Eng. abs.*, pp. 364-366).—A product having the chemical formula $C_{26}H_{42}O_6$ which has high activity as a follicular hormone was obtained from ergosterol. The chemical nature of the product is discussed with reference to the production of other related hormones synthetically.

A note on the presence in human pregnancy urine of an acid-hydrolysable combined form of pregnandiol, A. D. ODELL and G. F. MARRIAN (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1533-1535).—The presence of pregnandiol, a substance which can easily be converted into progesterone, was detected in human pregnancy urine.

FIELD CROPS

[Agronomic work in Connecticut] (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 199, 200-203, 204-206).—Brief reports are again (E. S. R., 75, p. 380) made on fertilizer tests with sweetpotatoes and potatoes (in cooperation with the [Connecticut] Storrs Station), and from research at the Tobacco Substation (E. S. R., 77, p. 330) concerned with irrigation of tobacco, soybean meal as a fertilizer for tobacco, effect of shade cloth on atmospheric conditions, harvesting tobacco at different stages of maturity, value of cotton hull ashes in the fertilizer formula, the effect of the element calcium, the optimum quantity of nitrogen to apply in fertilizing an acre of tobacco, and yield and quality as affected by fractional application of nitrogen.

Crops and soils information, H. B. BROWN, J. R. COTTON, D. C. NEAL, H. STONEBERG, J. P. GRAY, D. M. JOHNS, F. L. DAVIS, and H. C. LOVETT (*Louisiana Sta. Bul.* 285 (1937), pp. 47, figs. 5).—Experiments with crops and soils, conducted for various periods from 1926-36, inclusive, for which practical results are summarized included breeding work, variety, seed treatment, planting, spacing, cultivation, and subsolling tests; X-ray, boll weevil control, oil content of seed, root and fiber studies, and fertilizer experiments including placement, sources of nitrogen and phosphorus, and rates of applying nitrogen and potassium and formulas, all with cotton; variety, breeding, planting, fertilizer, and interplanting of soybean tests, all with corn; variety, planting, grazing, and inoculation tests with soybeans; variety tests with oats, lespedeza, peanuts, sorgo, grain sorghum, crotalaria, miscellaneous grasses, legume winter cover, and green manure crops; a fertilizer test with alfalfa; variety-planting tests with rice on dry land; crop rotations; residual effect of legume green manures and date of turning under soybeans for corn; and production tests with ramie, hemp, flax, sugar beets, cowpeas, *Lespedeza sericea*, and sunflowers.

[Field crops work in Nebraska] (*Nebraska Sta. Rpt.* [1936], pp. 8, 9, 11-16, 20, 21, 40, 42-44, 45, 46).—Activities (E. S. R., 75, p. 194) reported on from the station and substations included, in addition to work already noted, variety tests with winter and spring wheat, corn, oats, barley, grain sorghums, sorgo, alfalfa, soybeans, and Jerusalem-artichokes; breeding work with corn, wheat, alfalfa, and sweetclover; crop rotations; trials of manure at different rates for sugar beets; controlled freezing studies with winter wheat; potato storage; management of permanent pastures and native meadows; and weed control, including study of the nature of herbicidal toxicity. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

[Crop production in Nebraska] (*Nebr. State Bd. Agr. Ann. Rpt.*, 1936, pp. 167-213, 224-256, 258-262, figs. 15).—Papers dealing with agronomic problems, presented at the 1936 meeting of the Nebraska Crop Growers' Association, included An Agricultural Adjustment Program Based on Proper Use of Land, by O. V. Wells (pp. 167-173), and Plans for the Wider Use of Native and Introduced Grasses for Soil Conservation in Nebraska, by J. Fults (pp. 235-240) (both U. S. D. A.); Prospects for Greater Industrial Utilization of Farm Products, by L. M. Christensen (pp. 173-182) with discussion by T. A. Kiesselbach (p. 183) (Nebr.); Catch Crops and Special Crops for the State, by F. D. Keim (pp. 183-185), Some Successful Pasture Practices I Have Observed, by A. Peterson (pp. 224-229), Summary of the 1935 Nebraska Annual Pasture Contest, by A. Peterson and P. H. Stewart (pp. 230-235), Reserve Roughage When Pastures Fail, by R. R. Thalman (pp. 244-247), How Corn Varieties and Hybrids Yielded the Past Season, by T. A. Kiesselbach (pp. 248-253), Producing Hybrid Seed Corn on Nebraska Farms, by A. K. Gramlich

(pp. 253-256), and Plans, Policies, and Foundation Seed Distribution for Hybrid Seed Corn Production on Nebraska Farms in 1936, by P. H. Stewart (pp. 259-262) (all Nebr.); A Practical Program for Soil Conservation, by M. F. Miller (pp. 155-194) (Mo.); Grain and Forage Sorghums for Nebraska, by A. F. Swanson (pp. 194-206) (U. S. D. A. and Kans.); The Best Small Grains for Your Nebraska Farm, by C. A. Suneson (pp. 206-213) (U. S. D. A. and Nebr.); and The Part of Grass in the Husbandman's Program, by D. Marshall (pp. 240-244) (Ont.).

[Field crops research in Ohio] (*Ohio Sta. Bul.* 579 (1937), pp. 18-30, 31-33, 61-63, 68, 118-122, 123, figs. 3).—Experimentation with field crops (E. S. R., 75, p. 331) from which results are reported briefly was concerned with the effects of 20 years' cropping to different crop rotations on soil nitrogen and corn yields, by R. M. Salter; the merits of soybeans v. oats in the crop rotation, by L. E. Thatcher; comparisons of methods of summer seeding of seed mixtures, by C. J. Willard; the hill fertilization of corn, by E. E. Barnes; progress of the Ohio soil survey, by G. W. Conrey; the effect of closeness of grazing on the yield and stand of Kentucky bluegrass pasture, by D. R. Dodd, Thorne, a new red-chaffed, red-kerneled wheat for Ohio, by C. A. Lamb; experiments with hybrid corn, by G. H. Stringfield; the merits of Evergreen, a new late-blooming sweetclover, for pasture, by J. B. Park; the effectiveness of various chemicals as agents for the killing of weed seeds in seedbeds for lawns, by F. A. Welton; the effect of fertilizers upon the ash content of wheat, by E. G. Bayfield; the successful growth of corn in tank cultures, by J. D. Sayre and V. H. Morris; recovery of potato plants after severe injury from frosts, especially on muck soils, cooperative potato fertilizer experiments, sub-soil treatments for potatoes, and a new, high-yielding, late variety of potato, all by J. Bushnell; variation in the yield of corn and mixed hay from different seasons on limed and fertilized plats, by M. A. Bachtell and W. Mahan; an experiment on fertilizing alfalfa at seeding time, by Willard and H. W. Rogers; the increase in crop yield due to tile drainage v. no drainage and surface drainage, by Bachtell and H. S. Elliott; potato rotations, by Bachtell and W. E. Weaver; time and method of fitting alfalfa sod for wheat, by Bachtell and L. W. Sherman; eradication of field bindweed, by Willard and R. C. Beatty; the merits of alfalfa-timothy meadow as summer and fall pasture for dairy cows, by Bachtell and H. Allen; comparative yields and duration of alfalfa, alfalfa-timothy, and alfalfa-orchard grass mixtures, by Bachtell and R. Hopkins; bluegrass pasture problems in western Ohio, by Bachtell and P. A. Jones; and rotations for tobacco, by Bachtell and H. M. Wachter. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

The use of partial linear regression to analyze the curvilinear relationship between the yield of vegetable crops and the content of nutrients in the lower main stems, E. M. EMMERT (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 213-219, fig. 1).—This is a contribution from the Kentucky Experiment Station.

The utilization of Wabash clay (gumbo) soils in crop production, B. M. KING (*Missouri Sta. Res. Bul.* 254 (1937), pp. 42, figs. 13).—Crops of soybeans, rice, wheat, and oats were remarkably successful; winter barley (1934-36) made very high yields; whereas corn and clovers were mediocre or failed in most seasons in an experimental study of crop production on Wabash clay, commonly called "gumbo", centered on an 80-acre experiment field near Elsberry, Lincoln County, Mo., in cooperation with the U. S. Department of Agriculture. Varieties, cultural methods, and field practices are recommended for

growing the several crops on the basis of the experiments. The systems and methods of production on this field, it is pointed out, may be successfully repeated on other areas of Wabash clay and similar heavy bottom land in Missouri, provided such lands are protected from flood water and are given surface drainage sufficient to prevent rain water from standing in the fields for long periods.

A key to the grasses of Montana, based upon vegetative characters, C. L. HITCHCOCK (*Missoula: Author*, [1937], pp. [3] + 28, pls. 8).—This manual provides a key to the genera and species of grasses of Montana, with appropriate illustrations.

A comparison of some methods used in determining percentage utilization of range grasses, J. F. PECHANEC and G. D. PICKFORD (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 10, pp. 753-765).—Tests at Dubois, Idaho, of six methods used in the determination of percentage utilization of native grasses showed that the general reconnaissance method is not accurate enough, the stem-count method is neither accurate nor rapid for use on bunch grasses, the measurement method is not rapid enough for field use and not accurate enough for a check on ocular estimates, and because of labor involved and use of paired plats, the volume-by-weight method is not practical for use under range practices. Recommendations are that ocular estimate methods, on plats of limited size, supplemented by comparison with determinations made by the modified volume-by-weight method should be considered for pasture or open-range studies.

Foreign strains of alfalfa and red clover: What is their adaptability to Illinois? J. J. PIEPER and W. L. BURLISON (*Illinois Sta. Bul.* 431 (1937), pp. 473-503, figs. 12).—Comparisons of foreign strains of red clover and of alfalfa with domestic strains during 15 yr. (1922-36) of tests on experimental fields located in different parts of Illinois demonstrated beyond doubt that the foreign strains, except those from Canada, are not adapted to Illinois conditions. Planting them results in losses through immediate crop failures and the production of inferior hybrid strains caused by cross-pollination with domestic varieties.

In the whole series of tests a foreign strain of alfalfa seldom produced yields as high as those of the domestic check strain. Some yielded less than 25 percent as much as the domestic variety. This also applied to the Argentine and Turkestan strains, which evidently were better than the other unadapted foreign strains tested. Foreign strains of alfalfa in general made much poorer stands than the domestic checks, and the plants were subject to more severe attack by insects and disease and were more easily winter-killed.

Domestic strains of red clover used as checks yielded from 50 to 600 percent more than the several foreign strains. The foreign seed germinated well and made good stands the first year, but stands were soon lost because of winter-killing and susceptibility to disease and insect injury. The true inferiority of the foreign strains, except from Canada, showed up in inability to produce a crop the second year.

"Periods of high importations of alfalfa and red clover seed have in the past been followed by high percentages of failure and by declining acreages of these crops in Illinois. Tariff barriers and Federal requirements for coloring imported seed have tended to reduce importations during recent years, but whenever price differentials between domestic and foreign seed are high enough to make importing profitable, seed may be expected to come in over the tariff barriers."

Procedures other than the importation and use of unadapted seed in times of shortage of domestic seed are suggested for Illinois farmers.

Influence of delayed harvest on certain varieties of oats and barley in Michigan. H. C. RATHER (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 241-246).—Spartan, Wisconsin No. 38, Oderbrucker, and Glabron barleys, and Wolverine, Worthy, Markton, and Iogold oats were harvested 1931-33 beginning in the hard dough stage, i. e., first binder harvest, and continuing at about 3-day intervals for from 18 to 21 days.

Barley or oats which contains more than 30 percent moisture evidently has not yet attained maximum yield and will improve in yield and quality if let stand 3 or 4 days beyond the hard dough stage. The maximum yields of barley and oats were secured when the grain contained about 25 percent moisture with the grain and straw apparently fully ripe. Barley or oats left standing until dry enough for harvest with a combine will lose moderately in yield, and if combine harvest is delayed as long as 2 weeks from the fully ripe stage, losses will be rather severe. Spartan barley suffered the smallest losses due to delayed harvest and Oderbrucker the greatest losses. Markton oats appeared to shatter least of the oats varieties tested but lodged more readily than the others. Indications were that yield losses probably may be reduced materially if oats and barley are cut and windrowed at the fully ripe (25 percent moisture) stage, and cured in and threshed from the windrows with the combine.

Small grain and rye grass for winter pasture. R. H. STANSEL, P. B. DUNKLE, and D. L. JONES (*Texas Sta. Bul.* 539 (1937), pp. 38, figs. 3).—Experiments at the Angleton, Denton, and Lubbock Substations, in which wheat, oats, rye, barley, and ryegrass were sown in small plats and grazing simulated by clipping, showed the forage to be high in feed value, usually analyzing from 3 to 5 percent fat and about 25 percent protein at the beginning of the season and diminishing as the season advances. These crops have proved valuable for winter pasture and worthy of planting for their grazing value alone, although they are also (except ryegrass) dependable producers of grain.

Yields per acre measured in pounds of dry matter during the 4 yr. of the experiments have ranged up to 5,000 lb. for barley, 6,300 for wheat, 4,600 for oats, 4,400 for rye, and 6,900 lb. for ryegrass at Denton; up to 1,679 lb. for oats and ryegrass at Angleton; and at Lubbock around 3,000 lb. per acre for rye and almost as much for wheat, oats, and barley. Barley produced far more fall and early winter grazing than the other crops, but Italian ryegrass produced by far the largest amount of grazing in March, April, and May. Wheat, oats, and rye produced the best grazing for the midwinter months. The differences in rate of growth of the various crops indicate that maximum pasturage can be had by planting a mixture of the several crops. Wheat and ryegrass, more resistant than oats and rye to extreme cold, are preferable in north and northwest Texas, where grazing the wheat fields is already a common practice.

Grazing from these small grains becomes available in the fall just as the grazing from Sudan grass is declining and lasts well into the spring when the native grass pastures are ready for grazing. It usually is possible to change to native grass pasture from wheat and oats in time enough to avoid reducing the grain yields expected. At Denton, grazing up to March 1 improved grain yields and could have been continued 20 days with oats without damage to yields. At Lubbock, where 82 percent of the rainfall occurs between April and October, small grain for pasture is planted early in September and almost always yields some grazing, but generally it pays to withdraw the stock from pasture occasionally to allow the crop to recover.

Developing cutover pasture in the upper peninsula, B. R. CHURCHILL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 227-232, figs. 6).—An account of the success obtained by the Upper Peninsula Substation in developing pastures on cut-over land by burning over, pasturing with sheep, and seeding with appropriate mixtures.

Pasture renovation in relation to populations of white grubs, R. F. FUELLEMAN and L. F. GRABER (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 186-196, figs. 2).—Renovation, i. e., the establishment of dry-weather legumes (alfalfa, sweetclover, and red clover) in permanent bluegrass pastures without plowing, practiced by the Wisconsin Experiment Station in parts of 30 old bluegrass pastures in 1934 and 1935, resulted in very small populations of white grubs (due to egg depositions of June beetles occurring in May and June), and injury was practically eliminated, while in adjacent unrenovated grass, grubs usually were plentiful. Compared with untreated grass, 15 renovations in 1934 reduced the grub populations by an average of 98 percent and renovations in 1935 by 91 percent. Renovation was much more effective in reducing the populations of white grubs when it preceded beetle flights of 1934 and 1935 than when it preceded that of 1935 only. Dense growths of dry-weather legumes reduced populations effectively, whether these plants were in the seedling or later growth stages.

Embryo mortality in relation to seed formation in alfalfa (*Medicago sativa*), D. C. COOPER, R. A. BRINK, and H. R. ALBRECHT (*Amer. Jour. Bot.*, 24 (1937), No. 4, pp. 203-213, figs. 13).—In further studies at the Wisconsin Experiment Station (E. S. R., 76, p. 782), detailed observations were made on 10 alfalfa plants, 5 high seed producers and 5 low seed producers, grown under the same environment, to determine some underlying causes for failure of seed production.

Failure to set seed where the flowers have been tripped to insure pollination seemed due to lack of fertilization even though pollen tubes are present, failure of pollen tubes to reach all ovules, and abortion of embryos at various stages of development. High seed-setting plants averaged 1.25 seeds per flower tripped and 2.13 seeds per pod formed, whereas low seed-setting plants produced 0.07 seed per flower tripped and 0.99 seed per pod.

Although all ovules appeared to be in a similar stage of development at the open flower stage, about 35 percent of those in the high seed-producing plants became fertile v. 25 percent in the other group. A greater proportion of ovules at the stylar end of the ovary become fertile than at the base, due to the growth of the pollen tubes. A high percentage of the fertile ovules fail to develop into mature seeds, e. g., an average of 3.1 ovules per flower in the high seed-setting group fertilized resulted in only 1.25 seeds per flower at maturity, and in the low seed-setting group the averages were 2.5 fertile ovules and 0.07 seed per flower, respectively.

Many of the embryos abort at an early stage, i. e., in the proembryo or early embryo stage. The embryos of the low seed-producing plants develop more slowly, the cells are more highly vacuolate, and a higher percentage of abortion takes place than in the high seed-producing group. Meiosis and development of the megagametophyte is similar in the two types of plants, and starch is abundant in the embryo sacs of both types.

The effect of frequency of cutting on the yield of alfalfa under Hawaiian conditions, C. P. WILSIE and M. TAKAHASHI (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 236-241, fig. 1).—Cutting experiments with Hairy Peruvian alfalfa, made at the Hawaii Experiment Station, 1934-35, showed that cutting in the full-bloom stage outyielded cutting in the one-tenth to one-fourth stage,

which in turn gave higher yields than cutting in the bud stage. Indications were that under such conditions as prevail in Hawaii, with a year-round growing season, alfalfa to be fed green as a soiling crop probably will do best both in yield and persistence if cut in the full-bloom stage.

Corn and corn growing, H. A. WALLACE and E. N. BRESSMAN (*New York: John Wiley & Sons; London: Chapman & Hall, 1937, 4. ed., rev., pp. VII+486, figs. 117*).—In this revision and enlargement of a book noted earlier (E. S. R., 60, p. 433), particular emphasis has been placed on revisions dealing with the economics and genetics of corn.

Competition between cotton varieties in adjacent rows, J. R. QUINBY, D. T. KILLOUGH, and R. H. STANSEL (*Jour. Amer. Soc. Agron., 29 (1937), No. 4, pp. 269-279*).—Data recorded in cotton variety tests, 1927-34, at the Chillicothe and Angleton, Tex., Substations and at the Texas Experiment Station to determine the necessity of protecting one variety from competition of another by using guard rows, i. e., whether or not single-row plats can properly be used, indicated that, as a general rule, cottons grown in variety tests in Texas do not differ in ability to compete for moisture and plant food. Therefore, it seems desirable to employ single-row plats and to use the land so saved for additional replications. However, since differences in competing ability may exist, a random distribution of plats and good stands are essential if single-row plats are adopted.

Responses from various sources of nitrogen fertilizer, W. R. PADEN (*South Carolina Sta. Bul. 309 (1937), pp. 40, figs. 3*).—A strain of Cleveland cotton was grown continuously on Cecil sandy clay loam in small concrete-walled plats, receiving basal applications of superphosphate and potassium chloride (except where Ammophos, ammoniated superphosphate, and Nitrophoska were under test) and 15 different carriers as single sources of nitrogen and some of these in combinations. In 1928-30, the rate equaled 1,000 lb. of 5-10-4 fertilizer and in 1931-35, 600 lb. of 3.3-8-4. The soil, originally pH 5.58, was limed in two series at respective rates of 1,720 and 3,440 lb. of calcium hydroxide per acre. Rye was the winter cover on all plats except a few growing Austrian winter peas.

Only slight differences in soil reaction were observed following the use of the various nitrogen fertilizers. The average increase from lime was only 150 lb., or 7.5 percent, of seed cotton per acre, the greatest response from lime being secured with Milorganite, equivalent to 24.6 percent. On the unlimed plats the highest yield was secured from calcium nitrate and on the limed plats from cottonseed meal. No marked differences in the yields evidently are to be expected from use of various nitrogen sources on limed soil with a desirable reaction.

Certain single sources of nitrogen produced a higher average acre yield than their combination with cottonseed meal or with calcium cyanamide. From combinations with cottonseed meal and inorganic carriers on unlimed plats, the highest average yield was produced from a combination of nitrogen from cottonseed meal 30 percent, sodium nitrate 45, and ammonium sulfate 25 percent. Among similar combinations with calcium cyanamide the highest average yield was produced with nitrogen from calcium cyanamide 10 percent and from sodium nitrate 90 percent.

Applied at rates of 5 tons per acre each as nitrogen sources, 1928-35, green vetch produced an average of 2,610 lb. of seed cotton, cow manure 2,325, and no nitrogen 1,449 lb. Yields were increased slightly by use of 2 tons per acre of dry rye straw in combination with sodium nitrate, indicating that there was no serious temporary nitrogen starvation period from this combination.

Yields secured from Austrian winter peas in combination with varying amounts of sodium nitrate indicate that the amount of nitrogen in the fertilizer could be reduced about 50 percent without significantly affecting yields.

While considerable differences in the rate of accumulation of nitrate nitrogen were observed from use of the several materials, there was no close correlation between the rate of accumulation of nitrate nitrogen and the yield of crops.

Localization of pentosans in the resin glands of the cotton embryo, R. G. REEVES and J. O. BEASLEY (*Jour. Agr. Res. [U. S.], 54 (1937), No. 9, pp. 711-718*).—Further studies (E. S. R., 69, p. 203) at the Texas Experiment Station, involving many microchemical tests on leaves and embryos of upland cotton, gave strong indications that the resin glands are the chief containers of whatever pentosans are present in the cotton embryo.

Photoperiodism, a factor in determining the manurial efficiency and distribution of *Crotalaria juncea*, B. N. and S. N. SINGH and M. B. SRIVASTAVA (*Jour. Amer. Soc. Agron., 29 (1937), No. 2, pp. 123-133, figs. 5*).—The influence upon the green manurial value of *C. juncea* of different exposures to light was considered in further studies (E. S. R., 75, p. 477). The data were also analyzed in the light of Blackman's law of limiting factors (E. S. R., 74, p. 15) with a view to studying the light requirements of *crotalaria* and its energy economizing power.

With prolongation of time of light exposure, increase in the physical characters was observed, viz, plant height, number of leaves per plant, leaf area, root length, number and weight of root nodules, and length and yield of fiber. Certain characters attained their maximum development under continued illumination, while others required only 20 hours' exposure, longer exposure resulting in solarization. The critical light period for *crotalaria* apparently falls within the zone of a 16- to 20-hr. day. Beyond this range flowering was completely suppressed, the plant remaining purely vegetative. The crop's manurial efficiency rose with an increase in the length of the photoperiod, attaining its highest value under 20 hours' exposure.

During the early half of its life cycle *crotalaria* seems to require less light and plants growing under longer exposures cannot economize the entire energy falling upon them, but with further advance in age the light requirements increase. From these observations it is concluded that a photoperiod of from 16 to 20 hr. considerably increases the crop's manurial efficiency. If other environmental factors do not interfere, *crotalaria* can successfully be introduced as a green manure crop into regions with long periods of daylight and it may be grown to advantage in mixtures of early maturing crops.

[Potato production in Nebraska] (*Nebr. State Bd. Agr. Ann. Rpt., 1936, pp. 682-700, 703-731, 737-747, figs. 6*).—Papers presented at the 1936 meeting of the Nebraska Potato Improvement Association included A Review of the Disease Problems Confronting the Nebraska Growers of Certified Seed Potatoes, by R. W. Goss (pp. 682-690), Grade Defects—Their Prevalence in Nebraska Potato Stocks and Methods of Eliminating Them, by H. O. Werner (pp. 691-700), Practical Crop Rotations for Irrigation Potato Farmers, by L. Harris (pp. 703-707), and The Relation of Rainfall Distribution, Soil, Moisture, and Crop Rotation to the Yield of Potatoes at the Box Butte Experiment Farm, by H. O. Werner (pp. 715-731) (all Nebr.); Seasonal Uses of Water by Potatoes and Other Farm Crops Under Irrigation, by L. Bowen (pp. 707-714) (U. S. D. A.); and Maintenance of Organic Matter in Dry-Land Soils, by L. L. Zook (pp. 737-747) (Nebr. and U. S. D. A.)

Cellar and cold storage of sound and mechanically damaged Triumph seed potatoes. H. O. WEENIE (*Nebraska Sta. Res. Bul. 88 (1936), pp. 59, figs. 25*).—The relative desirability of cellar storage or cold storage during various periods was determined by considering the weight loss when Triumph potatoes were stored in crates and their field performance when planted.

The storage of sound potatoes.—Cold storage from harvest to planting resulted in less weight loss and in a higher percentage of sound potatoes than did cellar storage. With late-June planting, emergence was slightly slower from cold storage than from cellar-stored potatoes, but the stands and total yield were better. Cold storage within a few weeks or just after harvest, if continued until a week or two before planting, generally resulted in increased weight losses, because of greater rotting, but did not appear to affect yields the next year. When potatoes were placed in cold storage about the time cellars began to warm up or about when buds began to elongate into sprouts (in April), the most desirable and economical method used, losses due to sprout growth and decay were not serious, the percentage of sound tubers was almost as great, and yields were about as high as with longer cold storage. Cold storage beginning in late May or early June was less desirable than earlier transference to cold storage but preferable to continual cellar storage, provided sprouting was not advanced too far. When cold storage was begun in the fall, its continuance until early June was found desirable. A warming up period in the cellar of 2 or 3 weeks instead of from 5 to 7 days before planting increased weight losses, sprout growth, and usually the amount of decay, but generally did not increase yields significantly. Cold storage in spring was more essential for potatoes subjected to fall cold storage than for those that had fall cellar storage.

Storage losses under various treatments always were greater with immature tubers than with sound, mature tubers. Best stands and highest yields were generally secured from seed in which sprout growth was well initiated throughout the tuber. Solid, almost completely dormant potatoes produced better stands and yields than tubers severely shriveled because of extensive loss of water and sprout growth. Potatoes stored in sacks lost less weight during the fall and winter but more in the spring than those stored in crates. There was less sprout growth and rot with crate storage, probably due to differences in aeration.

The storage of mechanically damaged potatoes.—Weight losses were always greater with mechanically injured (E. S. R., 66, p. 31) than with sound potatoes stored under the same conditions. Under best conditions, sound potatoes in June constituted from 85 to 89 percent of the October weight with whole potatoes as compared with from 56 to 68 percent when tangentially cut tubers were stored. With cut potatoes, differences in weight loss generally were accounted for by the amount of rot. Losses in storage rose as the severity of the damage to tubers increased—the severity increased with the area of the cut or damaged surface. Exposure of cut potatoes to sunshine increased weight loss and amount of rot, especially as exposure was prolonged. Exposures to sunshine of from 4 to 8 hr. resulted in almost complete destruction of the potatoes by June when cellar storage was used. With cut surfaces turned away from the sun, exposure resulted in more loss than when cut tubers were taken into the cellar at once, but much less than when cut surfaces were toward the sun. Subsequent loss increased with length of exposure of such cut tubers to the dry air, wind, and sun. As the humidity of the cellar rose, the less was the weight loss and percentage of rot.

Cold storage any time before April 1 always resulted in increased weight loss and rot. Freshly cut potatoes held in a cellar 1 week and then moved to cold storage lost less weight than when put into cold storage just after cutting or if held in cold storage for only the first week just after cutting. Cellar storage until April 1 and cold storage after that gave satisfactory results but not much better than continual cellar storage. When potatoes were cut into seed-size pieces in early October, about half of the original weight remained as sound seed pieces by June 15. The losses generally increased as the severity of the exposure increased, due either to more time, brighter sunshine, less humidity, or more wind. Effects of exposure temperature were less apparent within the range of conditions experienced.

Studies in yield comparisons of rice, S. C. PEH (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 167-185, figs. 2).—Spacing experiments with rice at Lingnan University, Canton, China, 1934-35, showed yields to increase with closer spacings. Significant differences between yields were not observed when from 5 to 18 plants per hill were used. Indications were that for a fairly high yield the number of plants per hill should increase as the distance between hills is greater.

Effect of variety, maturity, and soundness on certain soybean seed and oil characteristics, J. F. O'KELLY and M. GIEGER (*Mississippi Sta. Tech. Bul.* 24 (1937), pp. 10).—Analyses revealed that in comparison with Mammoth Yellow, Biloxi, and Otootan soybeans grown under similar conditions, 1925-30, 1932, and harvested after threshing, Laredo had less fat and protein and more nitrogen-free extract and fiber and usually a higher refractive index and iodine absorption number.

Selections of Edible (in 1935) and of Mammoth Yellow (in 1933) soybeans were harvested when pods were green, mature, and dry enough for normal harvest. Beans harvested before maturity contained higher percentages of fat, protein, and fiber and lower percentages of nitrogen-free extract and often of ash than mature beans. Oil of these immature beans had a slightly lower refractive index and a considerably lower iodine number than the oil of mature beans, but saponification number showed no distinct trend.

Comparison of damaged and badly decayed soybeans of several varieties, the results of simulated harvesting and storage hazards, with sound beans, showed that as decomposition progressed the percentages of fat and protein increased and the percentage of nitrogen-free extract decreased, largely due to the decomposition of nitrogen-free extract. Increases in the refractive index were slight but the iodine number decreases were considerable. Decomposition of nitrogen-free extract and the formation of free fatty acids proceeded more slowly in a limited supply of oxygen than in a liberal supply. Germination seemed to produce the same changes as decay except that the iodine number was increased.

Besides the practical value of the findings as related to soybeans grown for oil, they are held to indicate the importance of proper methods of sampling for analyses.

Soybeans in the Northeast, R. G. WIGGANS (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 227-235).—Certain experimental results obtained at the [New York] Cornell Experiment Station in growing soybeans for hay, for silage (*U. S. R.*, 74, p. 329), and for grain indicated that the place of the soybean plant in northeastern agriculture is not entirely clear, but is promising enough to justify further studies within the area and further quest for more and better varieties suitable for the conditions. Planting tests with Cayuga soybeans, 1934-36, indicated that nine plants per square foot approaches closely

to the optimum rate with this variety and within the experimental limits, regardless of the row width.

Relation of nitrogen to yield of sugar-beet seed and to accompanying changes in composition of the roots, L. M. PULRZ (*Jour. Agr. Res. [U. S.], 54 (1937), No. 9, pp. 639-654, figs. 4*).—When U. S. No. 1 sugar beets, grown at St. George, Utah, received heavy applications of ammonium sulfate, increased yields of seed came from plants overwintered in the field, but the quality of the seed was not affected. Variations in date-of-planting and thinning modified the effects of the fertilizer. The nitrogen treatments evidently resulted in increased accumulation of sugar in the roots during the fall and in increased utilization of sucrose during the fruiting period in summer. Unfertilized plants accumulated sucrose during the summer and had a much abbreviated period of flower production.

Highly significant negative correlations were established between sucrose percentages in the roots at time of seed harvest and seed yields. The utilization of stored reserves in the sugar beet root has been found to depend upon the supply of nitrogen available to the plant during the fruiting period.

The influence of some climatological factors on seed-stalk development and seed yield of space-isolated mother beets, H. L. KOHLS (*Jour. Amer. Soc. Agron., 29 (1937), No. 4, pp. 280-285*).—The influence of temperature, precipitation, relative humidity, and hours of sunshine, 1926-27 and 1929-35, upon the percentage of beets that produced seed stalks and seed yield of space-isolated mother beets (E. S. R., 74, p. 33) was studied at the Michigan Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry. Periods and weather conditions found most favorable to a high percentage of beets with seed stalks comprised a cool (less than 69.4° F. maximum temperature), wet (more than 1.68 in. of rain), cloudy (less than 10.6 hr. of sun per day) May 16-31, with similar weather extending into the last half of June; and those most favorable to a high yield of seed were the same periods and conditions especially favoring seed stalk development and a cool (less than 81.4° maximum temperature), dry (less than 1.06 in. of rain) July 1-15.

The coumarin content of *Mellilotus dentata*, R. A. BRINK and W. L. ROBERTS (*Science, 86 (1937), No. 2219, pp. 41, 42*).—The nonbitter form of *Mellilotus* (E. S. R., 71, p. 471), reported from the Wisconsin Experiment Station, was identified as an annual flowering form of the typically biennial *M. dentata*, a species occurring sparingly from central Europe eastward to central Asia, usually on salty soils. Examination of 28 different lots (27 biennials), mostly from central Europe, showed that all are free of the characteristic bitter taste of common white sweetclover *M. alba*, and common yellow sweetclover, *M. officinalis*. No coumarin, mellilotic acid, or coumaric acid were detected in the vegetative tissues of *M. dentata* at the flowering stage, and if these substances are present at all in the leaves and stems the amounts are less than 0.001 percent. *M. officinalis* at the same stage of development contained coumarin 0.65 percent, mellilotic acid 0.25, and coumaric acid 0.036 percent, and corresponding values for *M. alba* were 0.36, 0.27, and 0.048 percent. A small amount of coumarin is present in seed of *M. dentata*, three stocks (Peiping, Copenhagen, and Moravia) showing 0.021, 0.074, and 0.04 percent, respectively, on the dry basis, while *M. officinalis* seed contained 0.63 percent and *M. alba* 0.46 percent.

Changes in breaking strength of straw of wheat varieties from heading to maturity, A. T. BARTEL (*Jour. Amer. Soc. Agron., 29 (1937), No. 2, pp. 153-156, fig. 1*).—Breaking strengths data were obtained on straw of Sonora, Baart, and Marquis wheat grown under irrigation at the Arizona Experiment Station,

1932-35, and cut close to the ground on alternate days from 6 days before one-tenth of the spikes were emerged until maturity. Salmon's technic and apparatus (E. S. R., 65, p. 734) were employed.

The data indicated that major differences in breaking strength may be determined on samples of straw harvested at any comparable stage from full heading to maturity when the varieties head on about the same date. However, breaking strength may be affected by environmental conditions under which plants grow. Thus, a late wheat grown under adverse conditions might be lower in breaking strength in comparison with other varieties than if all varieties grew under uniform environmental conditions.

The wheat meal fermentation time test with special reference to its reliability as a measure of quality in soft winter wheats, G. H. CUTLER and W. W. WOBZELLA (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 220-226).—Statistical studies made on comparable data derived from quality tests on 12 soft and semihard varieties of wheat grown at three locations in Indiana, 1930-33, and on 12 typical soft wheat varieties grown at the Indiana Experiment Station, 1931-34, revealed that the fermentation time test (E. S. R., 75, p. 776) appraised accurately the gluten quality of these wheats, giving consistent results from one year to another at all locations. Small differences were found in protein content and loaf volume in the soft wheats studied. These analyses and favorable results by other investigators indicate that the fermentation time test may be a reliable guide in measuring the relative gluten quality of soft winter wheats.

Aplopappus fruticosus or burro weed, B. I. JUDN (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 4, pp. 332-334, fig. 1).—Preliminary control experiments by grubbing and burning are reported.

HORTICULTURE

[Horticultural investigations at the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 169, 190-193, 200).—There are included brief progress reports on studies of spray residue on fruit, heredity in sweet corn, the development of hybrid varieties of sweet corn, the breeding of strawberries, improvement of squash by hybridization and selection, breeding of garden beets and peppers, and studies of the soil reaction requirement of different vegetables.

Eight-year summary of horticultural investigations, J. C. MILLER and W. D. KIMBROUGH (*Louisiana Sta. Bul.* 287 (1937), pp. 29, figs. 8).—Summaries are presented on the results of investigations, from 1929 through 1936, which for the greater part have been reported previously in greater detail. The crops discussed include asparagus, beans, cabbage, carrots, collards, okra, onions, peas, peppers, potatoes, sweetpotatoes, squash, tomatoes, oranges, strawberries, and tung oil.

[Horticultural investigations conducted by the Maryland Station] (*Maryland Sta. Rpt.* 1936, pp. XXXII-XXXIV, XXXV, XXXVI, XXXVIII-XLI).—Included are brief progress reports upon studies dealing with the physiological and biochemical changes in vegetables in storage (notably Hubbard squash); the polysaccharides in sweet corn; asexual propagation of the apple; cytogenetic studies in *Ipomoea*, *Gnadiolus*, and *Tulipa*; effect of culture on organic matter in orchard soils; the thinning of Concord grape clusters before blooming; peach pruning; effect of shade on the color of apples; spacing of strawberry plants; new varieties of fruits; canning tests of peas; effect of temperature on coloring of the tomato; relation of the plane of nutrition to yield of snap beans; culture

of vegetables at higher altitudes in the State; cut-off yields of various sweet corn hybrids and varieties; mulching of rhubarb with soybean hay; effect of cyanamide applied December 1 on subsequent crops of peas, lima beans, and wheat; selection of hardy strains of Virginia Savoy spinach; testing of rust-resistant snapdragons; and observations on bud drop in sweet pea varieties.

[Horticultural studies conducted by the Nebraska Station] (*Nebraska Sta. Rpt.* [1936], pp. 19, 20).—Brief reports are presented on the water requirements of apple trees, the effect of drought on the growth and distribution of fruit tree roots, and the root development and water requirements for asparagus.

Report of the division of horticulture, M. B. DAVIS (*Canada Expt. Farms, Div. Hort. Rpt.*, 1931-33, pp. 144).—Included in this general report (E. S. R., 66, p. 827) are the results of studies in fruit breeding; the nutritional requirements of fruits and vegetables; varieties of fruits and vegetables; pollination, propagation, and utilization of fruits; and cultural experiments with vegetables and ornamental plants.

Importance of organic matter in potting soils, C. E. HOXSIE (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 238-241, fig. 1).—In an attempt to produce poinsettia plants with large, showy blossoms, various fertilizer and organic matter treatments were followed. Of 24 plants grown in the soil and peat mixture, 15 attained a height of 30 cm or more, as compared with only 8 in the series which did not receive peat. With respect to the retention of foliage, the superiority of the plants receiving peat was striking. The addition of peat to the soil apparently permitted better penetration of water with more uniform distribution.

[Vegetable studies conducted by the Ohio Station] (*Ohio Sta. Bul.* 579 (1937), pp. 59-61, 63-68, figs. 2).—Information is presented on the water requirements of several vegetable crops, by D. Comin and J. D. Wilson; culture of garlic, and methods of applying fertilizer to sweet corn, both by Comin; the structure of tomato blooms, and the effect of supplemental illumination on the tomato, both by F. S. Howlett; effect of varietal, cultural, and other treatments on the content of mineral salts and vitamins in the tomato fruit, by I. C. Hoffman; and variety tests of tomatoes, by H. D. Brown and O. N. Riley.

The response of celery to manures and fertilizers, F. K. CRANDALL (*Rhode Island Sta. Bul.* 260 (1937), pp. 22, figs. 4).—Over a period of 13 yr. two 3-yr. rotations, one including stable manure in different amounts plus other fertilizers, and the second green manure crops plus fertilizers, were compared on a fine sandy loam soil the entire area of which had been treated with limestone to overcome acidity. On the whole, a striking response was found to stable manure as compared with green manures such as oats, clover, rye, wheat, and timothy. Comparisons between 8, 16, 24, and 32 tons of stable manure indicated that applications in the region of 16 tons are highly effective, but above this point the manure may become unprofitable unless obtainable at a very low cost. Attempts to substitute local peat composted with lime as a source of organic matter were not highly successful, the yields being about two-thirds of those secured with stable manure. Green manure plus fertilizer was not equal to stable manure plus fertilizer, but the results were sufficiently promising to encourage the grower who has no supply of stable manure. Increasing or decreasing the nitrogen content of the fertilizer used with stable manure resulted in significant changes in yield—more so than when used with green manure crops. Varying the phosphate content had no great effect on yield, suggesting that celery has a wide range of phosphorus utilization. Consistent effects were secured by modifications of the potash content of the supplemental fertilizer.

Bulb formation in some American and European varieties of onions as affected by length of day, R. MAGRUDER and H. A. ALLARD (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 10, pp. 719-752, figs. 9).—This is a more detailed presentation of the results of an investigation previously noted (E. S. R., 77, p. 188).

Anatomy and histology of the transition region in *Capsicum frutescens*, H. L. COCHRAN and F. F. COWART (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 9, pp. 695-700, pls. 5, fig. 1).—Using as material greenhouse-grown plants of the Perfection pimiento, the authors compared at the Georgia Experiment Station the changes that take place in the root-stem transition with that of several other members of the Solanaceae family hitherto studied. The results were said to be in full accord with those of Artschwager for *Solanum tuberosum* (E. S. R., 39, p. 629) as far as the phloem is concerned, but disagree with his findings regarding the xylem. The results of the study are presented in detail with supporting photomicrographs.

The yield complex of sweet corn, I, II, W. A. HUELSEN and W. H. MICHAELS (*Illinois Sta. Bul.* 432 (1937), pp. 505-608, figs. 20).—Seeking information that would be helpful from the standpoint of the cannery-contract grower, for establishing a basis for the determination of the proper degree of maturity for harvesting sweet corn, studies were carried on over 2 yr., 1931-32, with three varieties, Country Gentleman, Narrow Grain Evergreen, and Golden Bantam. The results are presented in two parts, as follows:

I. Effect of advancing maturity (pp. 511-581).—This study presents evidence that none of the three methods—(1) penetrometer reading, (2) moisture determination, and (3) the alcohol-insoluble residue test—is of material value to the grower. On the other hand, the percentage of dented ears was found a ready index. The first appearance of dented ears in Country Gentleman and Narrow Grain Evergreen occurred when the moisture content averaged 69.6 and 70.1 percent, respectively. The order in which a field of sweet corn matures, as indicated by the moisture content at the time when the yield of each component reaches a maximum was as follows in Country Gentleman and Narrow Grain Evergreen: (1) Number, weight, and percentage of prime husked ears, which is followed very closely by (2) weight and percentage of prime cut kernels, which coincides with the first appearance of dented ears, and (3) number and weight of sorted unhusked ears. The fact that sorted unhusked ears reached their maximum weights later than the other components is said to be a factor of major importance. Where tenderness is the objective, harvesting must be early because of the practical difficulty in grading ears into two grades, "whole-grain" and "cream-style" maturity.

II. Correlation analysis of the yield complex in sweet corn (pp. 581-600).—This section presents evidence that the principal yield components are closely associated. Sorted unhusked ears, prime husked ears, and prime cut kernels were closely associated, with prime husked ears and cut kernels, and also cobs, showing the closest correlation. Increases in mean ear weights are not associated generally with higher acre-yields. Mean weight per ear was only slightly correlated with the number of ears per acre. Increases in the yields of both ears and of cut kernels were accompanied usually by decreases in the weight of husked culls. Yields of cut kernels may be estimated from the yield of prime husked ears with sufficient accuracy for commercial purposes.

Sweet corn varieties and strains, R. G. ROTHGEB (*Canning Trade*, 58 (1936), No. 39, pp. 10, 12).—Information is presented on the yields of husked marketable ears, effects of rate and date of planting, etc., based on trials conducted by the Maryland Experiment Station.

Cut-off data for sweet corn varieties, H. B. COBURN (*Canning Trade*, 58 (1936), No. 39, p. 14).—Variety comparisons conducted for 2 yr. at the Maryland Experiment Station indicated that Golden Cross Bantam, Country Gentleman, and Top Cross Bantam yielded the highest cut-off, ranked in the order given.

Effects of carbon arc light on the chemical composition and vegetative propagation of tomato plants grown with a limited supply of nitrogen, J. W. MITCHELL (*Plant Physiol.*, 11 (1936), No. 4, pp. 833-841, figs. 3).—"The total carbohydrate content of the above-ground portion of tomato plants increased approximately 400 percent during a 10-day period in which the plants were grown with a nitrogen-free nutrient and exposed 12 hr. daily to light from a carbon arc lamp. In plants given a limited supply of nitrogen and illuminated with artificial light daily, sucrose, starch and dextrin, and polysaccharides concerned in the thickening of cell walls accumulated rapidly at first, then more slowly after several days of illumination, while the percentage of reducing sugars changed very little during the experiment. This decrease in the rate at which carbohydrates accumulated in the plants was accompanied by yellowing and abscission of the older leaves, thus decreasing the total leaf area per plant. This reduction in photosynthetic tissues may have been in part responsible for the decreased rate of carbohydrate accumulation during the latter part of the period in which the plants were grown in artificial light. There was an increase in the production and growth of roots by cuttings made from tomato plants grown in natural light of low intensity after the plants were exposed to arc light prior to making the cuttings. Cuttings made from such irradiated plants were less subject to decay than those taken from plants grown in natural daylight of low intensity during winter."

Seedlessness in tomatoes, L. R. HAWTHORN (*Science*, 85 (1937), No. 2199, p. 199).—Stating that in the winter garden region of Texas most varieties of tomatoes will with irrigation grow throughout the summer without setting any fruit, the author reports that in a cross between Large Cherry and Bonny Best, made by the Texas Experiment Station, there were some promising seedlings which set fruit during midsummer. During the hottest period the fruits became seedless, although earlier and later in the season seed production was normal.

Factors affecting the amount of puffing in tomatoes, S. H. YARNELL, W. H. FRIEND, and J. F. WOOD (*Texas Sta. Bul.* 541 (1937), pp. 64, figs. 6).—Experiments carried on in the greenhouse and field at the station and in the field under irrigation at the Weslaco Substation indicated that although environmental factors, such as soil moisture, air temperature, fertilization, and pollination, influenced the amount of puffing in tomatoes, the use of varieties and strains selected for their ability to produce normal fruits under southern conditions and the development of new low-puffing varieties by breeding seems to offer the only practical solution to the problem. The proportion of affected fruits varied greatly, from 0 to 100 percent, depending on hereditary and environmental factors.

Under controlled greenhouse conditions, when high temperature was not a factor, plants with low available moisture produced less puffed fruits than did those with abundant moisture. The differences were most marked in the early fruiting period. The same relationship was found in only a part of the irrigation experiments at Weslaco. A general positive relationship was observed between the amounts of rainfall and of puffed fruits. Plants sprayed with bordeaux mixture alone had less puffed fruit than comparable plants

sprayed with bordeaux plus heavy oil. Where maximum temperatures in the greenhouse exceeded 100° F., puffing approached 100 percent, irrespective of water treatments. When maximum temperatures remained below 100° there was some indication that low temperature in March contributed to puffing.

In regard to nutrition, plants grown in soil obtained from the north behaved no differently as to puffing than those grown in local soil. However, less puffing was noted in every case at the station where a 6-12-6 fertilizer was used. At Weslaco, fertilizers had inconsistent effects and supplements containing magnesium or iron had no significant influence. No correlation could be established between the occurrence of puffing and pathogenic troubles. Hand pollination of Marglobe in the field reduced the amount of puffing and probably explains excessive puffing at temperatures above 100°.

From the genetic aspect, small-fruited tomatoes, with the exception of Pomodora, had little or no puff. Among large-fruited varieties, considerable differences were noted, Kanora, Marketeer, and Success being examples of low-puffing and Marglobe of high-puffing varieties. Differences were also noted between strains of single varieties. Observations on crosses between susceptibles and nonsusceptibles indicated that several hereditary factors, for the most part recessive, are involved.

[Pomological investigations conducted by the Ohio Station] (*Ohio Sta. Bul.* 579 (1937), pp. 54-58, fig. 1).—Brief progress reports are presented on apple breeding, by F. S. Howlett; control of fire blight, and the length of pre-bloom spraying period in apples, both by C. W. Ellenwood; the comparative resistance of peach, grape, and plum varieties to winter cold, distribution of peach roots in different soils, and the effects of different systems of culture on the number and diameter of raspberry canes, all by L. Havis.

A fruit circimeter, A. F. PILLSBURY and O. C. COMPTON (*Calif. Citrogr.*, 22 (1937), No. 4, pp. 151, 156, figs. 2).—The construction and use of a circumference gage developed at the Citrus Experiment Station, Riverside, are discussed.

Soil organic matter and porosity of an orchard soil under different cultural systems, L. HAVIS and J. H. GOURLEY (*Soil Sci.*, 48 (1937), No. 6, pp. 413-420, fig. 1).—Determinations at the Ohio Experiment Station by the chromic acid method of the organic matter in soils from orchards maintained for many years under (1) tillage with cover crops, (2) mulch, and (3) bluegrass sod showed about the same content of organic matter under the mulch and sod with a much lower content in the cultivated section despite the plowing under of cover crops. Using volume-weight and rate of water absorption as a measure of water mulch, sod, and cultivation were arranged in descending order of porosity. In each case the difference between the results under cultivation and under sod was greater than those under sod and under mulch.

Root development of 25-year-old apple and pear trees [trans. title], T. ROEMER and F. HILKENBÄUMER (*Kühn Arch.*, 42 (1937), pp. 281-303, figs. 37).—An examination of the root systems of six varieties of pear worked on quince and of four varieties of apple worked on Golden Metz Paradise rootstocks showed in the apple the greater amount of the roots to be located in the 30-50 cm soil zone and in the pear in the 25-40 cm zone. There was noted a definite influence of the scions on the root development, in the amount of fibrous roots, and in the structure and form of the root development. The influence of the scions appeared to be qualitative rather than quantitative. The knowledge of root growth is believed useful in establishing cultural and fertilizer practices with fruits.

Cultural systems for the apple in Ohio, C. W. ELLENWOOD and J. H. GOURLEY (*Ohio Sta. Bul.* 580 (1937), pp. 33, figs. 10).—Stating that various systems of orchard culture are in use in Ohio and that there are more commercial apple

orchards in sod or some permanent cover than under any other system, the authors bring together the results of long-time investigations carried on in different parts of the State. Yields were maintained at a satisfactory level in a mixed-variety orchard at Wooster which had been in mulch for many years. Comparisons in a Stayman Winesap-Delicious orchard planted in 1915 and immediately given differential cultural treatments showed, at the end of 1935, greater production of Stayman Winesap and less of Delicious in the tilled cover-cropped than in the mulched area. Color was affected very slightly. Size of fruit was larger on the mulched area. Cost of production on a bushel basis was about the same, and growth was not greatly different. Soil temperature was higher during summer and lower during winter in the tilled area. The date of full bloom for both varieties was the same on both areas. In August of the very dry year of 1930, moisture was much higher beneath the mulch.

Studies of root distribution and penetration under different cultural treatments showed no tendency toward shallow rooting in mulched orchards. There was observed a downward and outward gradient of roots from the trunk and a tendency of the roots to spread rapidly over the whole orchard area, suggesting the advisability of wide-spread applications of fertilizer.

Based on the results, information is presented on tile drainage, cover crops, cultivation implements, prevention of erosion, the maintenance of organic matter, etc.

Blooming and ripening dates with yields of 360 varieties of apples grown at Mountain Grove, Missouri, P. H. SHEPARD (*Missouri Fruit Sta. Circ.* 25 (1937), pp. 15).—The data are presented chiefly in tabular form and show that among well-known apple varieties Willow Twig, York Imperial, and Golden Delicious were the most productive kinds with average yields of 240, 220, and 220 bu. per acre, respectively.

Spray residue on apples, R. H. ROBINSON (*Indus. and Engin. Chem.*, 28 (1936), No. 4, pp. 455-457, fig. 1).—In this contribution from the Oregon Experiment Station, the author discusses the present status of research on the removal of toxic residues from apples, and suggests that heavily sprayed waxy fruits that cannot be cleaned by the usual hydrochloric acid and sodium silicate treatments may be washed effectively in acid solution supplemented by petroleum oil. White oils that have a sulfonation test of 90 or above and a viscosity between 40 and 50 Saybolt are recommended. A temperature between 100° and 105° F. should be maintained for maximum effectiveness. Wetting or degumming agents when used properly in combination with hydrochloric acid increased the solvent action of the acid in the spray residue.

Types of peach buds in relation to nursery practice, W. H. UPSHALL (*Sci. Agr.*, 17 (1937), No. 7, pp. 445, 446, fig. 1; *Fr. abs.*, p. 446).—A comparison made at the Horticultural Experiment Station, Vineland, Ontario, between single and double or triple buds taken from bearing trees of Valiant, Veteran, and Elberta varieties showed, in the first two varieties, striking gains in the percentage of developing buds in favor of the double and triple bud groups. It is recommended that nurserymen do not use plump single buds from bearing peach trees.

Embryo abortion in the peach in relation to chemical composition and season of fruit ripening, H. B. TUKEY and F. A. LEE (*Bot. Gaz.*, 98 (1937), No. 3, pp. 586-597, figs. 2).—Embryos of 10 peach varieties with seasons extending from early to late were examined and chemically analyzed at or near fruit maturity, and, for comparison, embryos of a single late variety (Elberta) were analyzed periodically throughout the season.

Elberta embryos were flaccid during the second stage of fruit development, so that the seed became shriveled when removed, but at maturity the embryos were firm and completely filled the integuments. Embryos of the earliest-ripening sort were abortive and disintegrated at fruit ripening, while those of each successively later-ripening variety were larger, firmer, and more nearly filled the integuments. At fruit ripening, embryos of a late-ripening sort contained 45.03 percent of moisture, 30.67 of fat, 2.6 of nitrogen, 2.32 of sucrose, and 0.23 percent of reducing sugars. Embryos of early-ripening varieties exhibited a higher moisture content and lower contents of fat, nitrogen, reducing sugars, and sucrose. There was a steady increase in growth, moisture loss, and accumulation of stored materials in embryos of all varieties, and an abrupt check in these processes as the ripening date for each successive variety was reached. If the moisture, fat, and nitrogen contents of the embryos are plotted with reference to time of ripening, the composite graph is similar to that for the development of a single variety. The close similarity observed in the growth of embryos of different varieties, regardless of the fruit ripening season, extends as well to the chemical changes within them.

Delayed thinning as an aid in controlling the gumming of the Phillips Cling peach. L. D. DAVIS (*California Sta. Circ. 341 (1937), pp. 14, figs. 11*).—Together with certain related portions of the case history of the disease, information is presented on a practical control which was found to reduce the incidence of the disease by from 80 to 90 percent. Four types of gumming, (1) the result of injury from insects, limb rub, etc., (2) early suture gumming, (3) distal and dorsal, and (4) late ventral, are described and discussed. The first type is not specific to the Phillips Cling, the second occurs more frequently on Phillips Cling than on other varieties but is relatively rare, the third is by far the most frequent, and the fourth is moderately abundant. The period of gumming was found consistent from year to year, and from 85 to 90 percent of the injury occurred in the 35-day period following the beginning of the time that the pit begins to harden at the tip and about three-eighths of an inch along the ventral suture. This stage may be determined by the resistance offered to a sharp knife and by an examination of the ovule or kernel. The addition of 2 weeks to this pit-hardening stage, designated in the text as the reference date, determined fairly accurately the beginning of the severe gumming period. By delaying thinning until most of the gumming had taken place, practical control was obtained for two reasons—(1) a heavy set of fruit on the tree during gumming apparently protects a certain number of fruits from the injury, and (2) thinning after most of the injury has occurred permits the removal of the gummy fruits.

Peach production in Ohio. L. HAVIS and J. H. GOURLEY (*Ohio Sta. Bul. 581 (1937), pp. 41, figs. 10*).—Including the results of pertinent investigations, this bulletin presents general information for the orchardist with regard to economics, propagation, favorable locations, varieties, planting, soil management, root distribution in different soils, fertilizers, pruning, fruit thinning, winter injury, and harvesting and marketing.

In a fertilizer study conducted at Danbury on a soil of rather poor native fertility, nitrate of soda, sulfate of ammonia, and nitrate of potash all gave good results, the yields from equivalent amounts of nitrogen being much the same. Splitting the application into an April and June treatment exerted no noticeable effect on tree growth or yield. Tankage plus bonemeal did not prove as effective as did the inorganic materials. Nitrogen fertilizer greatly improved the set of fruit from about 17 percent on the nonfertilized to 30-odd percent on the treated trees. Applications of inorganic nitrogen delayed ripen-

ing from 3 to 7 days, while in 2 or 3 yr. organic nitrogen had little or no effect. Nitrogen, except in 1 yr., 1925, failed to influence greatly the size of peaches but did increase the actual number of bushels of peaches in the larger grades. Inorganic nitrogen improved the keeping quality of peaches slightly.

A pruning experiment in a young peach orchard on Catawba Island showed that heavy pruning as compared with light pruning reduced yields materially.

Influence of cultivation on the growth and yield of blueberry plants, S. JOHNSTON (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 232-234, fig. 1).—In the spring of 1935, certain Rubel blueberry plants grown since the establishment of the plantation under a system of clean cultivation, complete fertilizer, and cover crops after harvest were allowed to grow up to grass and weeds. Fertilizer treatments were continued, and the grass cover cut twice and allowed to remain where it fell. In 1936, a season characterized by a long drought, the 68 plants in sod yielded 53 qt., averaging 1,165 berries, as compared with 156 qt., averaging 873 berries, for a comparable number of tilled plants. Indications as to new growth pointed to similar results in 1937 and, on the whole, suggested that on sandy soils, such as used, cultivation should be employed through the harvest period with subsequent cover crops to maintain the organic matter.

Growing raspberries in West Virginia, H. E. KNOWLTON, W. H. CHILDS, and C. R. OBRON (*West Virginia Sta. Circ.* 72 (1937), pp. 24, figs. 12).—Information of a general nature is offered on economic considerations, varieties, the establishment of plantations, propagation, pruning, soil management, fertilizers, harvesting, and diseases and their control.

Disposing of raspberry prunings by means of an ensilage cutter, H. A. CARDINELL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 234-238, figs. 4).—A description is presented of a method of disposing of raspberry prunings wherein the material is run through a silage cutter and returned to the soil as a source of organic matter. No evidence was seen that the prevalence of disease was in any way augmented by the application of prunings.

Blooming and ripening dates with yields of 167 varieties of grapes grown at Mountain Grove, Missouri, P. H. SHEPARD (*Missouri Fruit Sta. Circ.* 27 (1937), pp. 8).—This consists, for the most part, of tabulated data indicating that Dunkirk, Muench, and Hartford were the three most productive grape varieties, with estimated yields of 11,880, 11,520, and 11,340 lb. per acre, respectively.

Vegetative propagation of tropical and sub-tropical fruits, compiled by G. St. C. FEILDEN (*Imp. Bur. Fruit Prod. [East Malling, Kent], Tech. Commun.* 7 (1936), pp. 67, figs. 12).—Briefly describing the important methods of asexual propagation, the author presents specific information for a large number of fruits.

Propagating the avocado by means of stem cuttings, E. R. EGGERS and F. F. HALMA (*Calif. Avocado Assoc. Yearbook*, 1936, pp. 63-66, figs. 3).—A fair percentage of cuttings taken from 2-year-old Mexican nursery seedlings rooted successfully, but with the Fuerte and Nabal varieties failure resulted from attempts to root comparable material or to use marcottage.

Growth of the avocado tree in solution culture, A. R. C. HAAS (*Calif. Avocado Assoc. Yearbook*, 1936, pp. 66-69, fig. 1).—Information is given on the solutions and methods employed in growing healthy avocado trees in nutrient cultures.

The effect of ringing on the carbohydrate and nitrogen content of Mexican avocado seedlings, R. TIGHEO (*Calif. Avocado Assoc. Yearbook*, 1936, pp. 69-72).—Dry weight was consistently lower in the roots and higher in the

tops of ringed than unringed trees. Root-top ratio calculated on both a fresh and dry weight basis was always higher in the unringed trees. Starch was higher in the tops of ringed trees, even that in the leaves being slightly but significantly greater. The effect of ringing on free and total reducing substances was rather slight, and that on total nitrogen was similar thereto.

Pectin in avocado leaves, A. R. C. HAAS (*Calif. Avocado Assoc. Yearbook, 1936, pp. 72-74*).—A wide range was found in the percentage content of pectin in avocado leaves of different varieties. Leaves affected with tipburn had an apparently higher content of pectin than did healthy leaves of the same variety.

Chemical composition of avocado fruits, A. R. C. HAAS (*Jour. Agr. Res. [U. S.], 54 (1937), No. 9, pp. 669-687, figs. 6*).—Following an earlier paper (E. S. R., 76, p. 43), in which it was shown that the number of stomata, the water loss, and the permeability of avocado fruits were greater toward the tip end, the author discusses, from the California Experiment Station, the composition of the different portions of fruits of several varieties. No consistent difference was observed between the fat content of the stem and tip halves of the pulp of avocado fruits. In the case of Fuerte avocados, the tip halves of the pulp usually contained on a fresh-weight basis slightly higher percentages of dry matter and of ash in the dry matter than did the stem portions. Potassium, the most abundant constituent of the ash, occurred in greater concentration in the tip portions. Both sodium and calcium occurred in only small amounts, but the direction of the calcium gradient in the pulp halves appeared to be opposite to that of potassium. The differences in iron content between the halves appeared to be statistically insignificant. Inorganic phosphate and also manganese decreased as the fruit matured. The percentages of total nitrogen were greater in the dry matter of the tip than of the stem half. Total sulfur and total chlorine on the percentage basis were greater in the stem than in the tip halves of the dry matter of the skin of avocado fruits, and the author suggests the possibility that chlorine may be involved in the break-down of the tissues of the skin of overripe fruits. Varieties showed considerable difference in their percentage composition of various combinations of materials.

The anatomy and histology of the bud-union in citrus, K. MENDEL (*Palestine Jour. Bot. and Hort. Sci., 1 (1936), No. 2, pp. 13-46, figs. 7*).—The results are presented of examinations of samples of unions of the Shamouti orange budded on sweet lime and sour orange roots, collected at intervals from 1 day to 6 mo. after budding. The process of union formation could not be separated into a preliminary and a final stage but represented an apparently continuous process.

Phosphorus content of citrus and factors affecting it, A. R. C. HAAS (*Soil Sci., 41 (1936), No. 4, pp. 239-257, pl. 1, figs. 3*).—Analyses by the Citrus Experiment Station, Riverside, Calif., of lemon fruits at all stages of development showed the highest percentage of phosphorus in the flowers. When tree-ripe fruits were eliminated, there was found a decrease in the percentage of P in the dry matter as maturity advanced. Lisbon lemons at comparable stages contained less P than Eureka lemons. The dry matter of the peel of lemons contained a higher percentage of P than did that of the peel of Valencia and Washington Navel oranges. Nitrate of soda fertilizer was found to result in an increased percentage of P in the peel and pulp of Valencia oranges and of lemons. P-free culture solutions permitted the growth of orange fruits but resulted in a marked reduction in the percentage of P in the dry matter of the peel.

Mottled citrus leaves in every case contained markedly higher percentages of P than did healthy leaves, and the leaves of trees receiving the largest applications of nitrogen contained the lowest percentages. This indicated that determinations of P in the leaves are not of themselves adequate for determining the needs of the leaves for phosphate. The percentages of inorganic P in citrus leaves exceeded in every case the organic and phospholipide fractions.

Potassium in citrus leaves and fruits, A. R. C. HAAS (*Calif. Citrogr.*, 22 (1937), No. 4, pp. 154, 156, fig. 1).—Data contributed by the Citrus Experiment Station at Riverside on the potassium content of the peel and pulp of orange and lemon fruits harvested from differential fertilizer plats suggest that differences in composition may be related to the potassium fertilization of the soil. On the whole, the peel of citrus fruits appeared to be the best index so far discovered in regard to potassium absorption as related to soil fertilization.

Developmental studies of the pineapple *Ananas comosus* (L) Merr.—I, Origin and growth of leaves and inflorescence, K. R. KEENS, J. L. COLLINS, and H. KIM (*New Phytol.*, 35 (1936), No. 4, pp. 305–317, pl. 1, figs. 6).—The first visible evidence of an inflorescence is the increase in size of the meristem at the apex of the axis. The average period of time for completion of inflorescence formation and growth and the several divisions of these processes were determined. The inflorescence begins development before the peduncle starts elongation. The phyllotaxy of the large and small fruited varieties is noted. The time when the phyllotaxy changes from that of the leaf-producing to the inflorescence growing point is considered a critical one for the production of fruit and crown abnormalities.

Some effects of root-pruning on transplanted pecan trees, C. L. SMITH and J. HAMILTON (*Okla. Pecan Growers' Assoc. Proc.*, 1936, pp. 26–30).—Based on observations the following January when dug, the cutting in early spring of 1934 of the taproots at 30 in. depth of Squirrel Delight pecan trees, the rootstocks of which were 5 yr. old and the tops 2 yr., resulted in an increased growth of the lateral roots and in most cases in the formation of new roots from the callus. Other trees with their taproots cut in autumn showed little or no callusing and some injury from termites and rots. Top growth the year following transplanting was greater in the spring root-pruned group than in either the autumn group or in unpruned controls. A repetition of the test in 1935 with Govette trees gave different results in that the spring root-pruned gave the poorest results as measured in subsequent top growth. In this case the greatest shoot growth was made by the trees root-pruned on August 29. Mortality was much higher in the unpruned controls than in any of the other groups. In the case of Schley trees in which all the laterals were cut off close to the taproot when transplanted, insignificant root growth occurred during the subsequent 2 yr. as compared with trees the laterals of which were unpruned. Top growth was proportionate to root growth. Some indication was observed that certain chemicals were highly effective in inducing root growth in root cuttings.

Morphological development of pecan buds, G. F. GRAY (*Okla. Pecan Growers' Assoc. Proc.*, 1936, pp. 69–74, figs. 10).—Stating that the pecan differs from the fruit trees in producing two different types of blossom buds, staminate and pistillate, the author discusses and depicts the several stages in the development of each type of bud. The pistillate buds are differentiated in late March or early April of the year they blossom, whereas the staminate flower buds are evident by microscopic examination 6 to 12 mo. prior to bloom.

Mint culture in northern Indiana, N. K. ELLIS (*Indiana Sta. Circ.* 227 (1937), pp. 12, figs. 8).—This pamphlet presents general information on varieties, propagation, culture, fertilizers, harvesting, distillation, and the control of pests.

[Floricultural investigations by the Ohio Station] (*Ohio Sta. Bul.* 579 (1937), pp. 69-72).—Among studies, brief reports upon which are presented, are photoperiodic effects on different flowering plants, including the chrysanthemum, gardenia, and aster, by G. H. Poesch and A. Laurie; control of chlorosis with iron salts, by L. C. Chadwick and Poesch; use of growth-promoting substances in propagation, by Poesch; effect of cloth tents on the growth of asters, roses, chrysanthemums, hydrangeas, and gardenias, by C. B. Link; and the effects of preheating gladiolus corms upon the time of flowering, by G. R. Mann and Laurie.

Old garden roses, E. A. BUNYARD (*London: Country Life, Ltd.; New York: Charles Scribner's Sons*, 1936, pp. XII+163, pls. [33]).—Historical, botanical, and other pertinent information is presented.

Hill's book of evergreens, L. L. KUMLIEN (*Dundee, Ill.: D. Hill Nursery Co.*, 1936, pp. XIV+304, [pls. 2], figs. [339]).—Information is presented on the botany, propagation, pruning, culture, and utilization of narrow-leaved evergreens.

FORESTRY

[Forestry investigations at the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 188, 189, 190).—General statements are presented with regard to activities in the propagation of forest nursery stock and its distribution, management of State forests, and the seasoning of maple posts.

[Forestry investigations conducted by the Ohio Station] (*Ohio Sta. Bul.* 579 (1937), pp. 124-132, figs. 2).—Included are brief reports on activities in the development of State forests and parks, reforestation activities, and species response to dangerously low winter temperatures, all by E. Secrest; the restocking of grazed woodlands, by R. R. Paton and Secrest; improvement cuttings and replantings in the State forests, by O. A. Alderman and F. S. Shulley; and forest fire control, by B. E. Leete.

Pot culture tests of forest soil fertility, H. L. MITCHELL (*Black Rock Forest Bul.* 5 (1934), pp. XI+138, pls. 11, figs. 11).—In these experiments Scots pine seedlings were grown under conditions of controlled radiation in sand and in sand plus raw humus, both supplied with basic nutrient cultures with only the nitrogen varied. In addition, white pine seedlings were grown in sand and in forest soils with various omissions of nitrogen, phosphorus, potassium, and calcium. Initial seed weight was found an important consideration requiring a mathematical correction.

The yields of Scots and white pine seedlings in sand were found to vary directly with the nitrogen concentration in the nutrient solution. Maximum growth was made at a nitrogen concentration of 300 p. p. m., and at this point the internal nitrogen concentration approximated 3.2 percent in both species. The proportion of root to shoot attained a maximum when the nitrogen content was 50 p. p. m. in the nutrient solution. The internal nitrogen supply is believed to be more important in determining yields than the external supply. Increases in radiation intensity from 50 percent to full light increased dry weights of Scots pine only when abundant nitrogen was present in the cultural medium.

Root growth in natural soils did not behave as in the sand, a fact thought associated with mycorrhizal development. In the different radiation treatments, it was observed that with less than 55 p. p. m. of nitrogen in the nutrient solu-

tion, increased radiation did not give increased growth. In the investigation of white pine in the four native soils, there was indicated a marked lack of phosphorus in all four soils, with some differences in the amount of available nitrogen. Seedlings grown without adequate nitrogen were yellowish, those with insufficient phosphorus were distinctly purple.

Studies on the development of conifers in raw humus.—III, The growth of Scots pine (*Pinus silvestris* L.) seedlings in pot cultures of different soils under varied radiation intensities, P. R. GAST (*Meddel. Statens Skogsforsöksanst. [Süeden]*, No. 29 (1937), pt. 7, pp. 587–682, figs. 22).—Carried on partly in Sweden and partly at the Harvard Forest, Petersham, Mass., these experiments deal with the effects of simultaneously varied mineral nutrition and radiation on the growth of Scots pine and white pine seedlings growing in cultures of sand, sand and humus, and humus of high and low quality. Among conditions affecting the growth of seedlings was the weight of seeds, necessitating the use of a correction factor.

The level of radiation intensity was found to be of major importance in determining dry weight at intensities less than about 20 percent of that normally received in temperate, humid regions north of 40° latitude. With radiation intensities above 30 percent, nutrients became more important. Scots and Corsican pines were more responsive to nitrogen increments than was white pine. It was evident that at moderately high radiation intensities an increase in nitrogen availability can offset a deficiency in radiation. In fact, nitrogen supply may become the limiting factor to increased growth under conditions of abundant radiation. A radiation intensity of about 20 percent of full sunlight, equivalent to approximately 5–7 kg calories per square centimeter on a fixed horizontal surface through June, July, and August, is conceded the minimum supply from which Scots pine will develop a vigorous root system and a well-balanced top-root ratio. There was some indication that seedlings planted in a low-grade raw humus actually are drained of a part of their reserves.

The application of the findings to silvicultural management is discussed.

Increasing growth and yield of young spruce pulpwood stands by girdling hardwoods, M. WESTVELD (*U. S. Dept. Agr. Circ. 431* (1937), pp. 20, figs. 4).—An experiment in girdling overtopping hardwoods in a mixed spruce-hardwood stand in central New Hampshire showed, 30 yr. after the initial treatment, a greatly increased volume of red spruce. There were 1,607, 974, and 172 cu. ft. of spruce per acre on the heavily girdled, moderately girdled, and no-treatment plats, respectively. Because of the heavy stand of spruce just below merchantable size on girdled areas, much larger increments are expected on these plats in succeeding years than on the check areas. The stand on the moderately girdled plats possessed, however, the greatest total volume of merchantable woods of both conifer and hardwood species.

From the viewpoint of profitable returns, it is estimated that in 1945, when the bulk of the spruce has attained merchantable size, the net gain in conifer pulpwood volume will be 23 and 13 cords per acre, respectively, on the heavily and lightly girdled plats, as compared with the controls. In conclusion the authors point out that selective girdling has been found effective in improving mixed spruce-hardwood stands, particularly in a region where hardwoods have market value. It is possible, wherever a satisfactory understory of conifers exists, to convert by girdling a mixed stand into a pure stand of conifers. A series of properly timed girdling operations has an advantage over single severe treatments because of decreased hazards caused by wind, sun, and frost.

Stumpage and log prices for the calendar year 1935, compiled by H. B. STEER (*U. S. Dept. Agr., Statis. Bul. 57 (1937), pp. 56, figs. 3*).—This is the usual statistical report (*E. S. R.*, 75, p. 206) upon price levels and demands for stumpage and logs during the calendar year 1935.

DISEASES OF PLANTS

The Plant Disease Reporter, July 1 and 15, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 21 (1937), Nos. 12, pp. 221-235; 13, pp. 237-257, figs. 8*).—The following items of interest are included in these issues:

No. 12.—Relative prevalence and geographical distribution of various ear rot fungi in the 1936 corn crop, by P. E. Hoppe; reports on wheat stem rust from Virginia, Wisconsin, Iowa, and the Middle West; notes on *Cercospora* foot rot and loose smut of wheat in Oregon and Washington, by R. Sprague; reports on wheat diseases in Massachusetts, anthracnose on rye in Wisconsin, mildew on barley in Iowa, and bacterial wilt on sweet corn on Long Island; survey of tobacco plant bed diseases in Florida, 1937, by R. R. Kincaid; tobacco plant bed diseases in western Kentucky, by E. M. Johnson; tobacco seedbed survey in Wisconsin, 1937, by J. Johnson; disease survey notes for Massachusetts, by O. C. Boyd; fruit disease situation in northern Virginia, by A. B. Groves; apple diseases in Wisconsin, by R. El. Vaughan; reports on pea mosaic on Long Island, root rot of peas in Wisconsin, cabbage diseases in New York, downy mildew on onion in Massachusetts, onion smut in New York, and clover anthracnose in Wisconsin; willow scab (*Fusicladium saliciperdum*) prevalent in Vermont, by H. L. Bailey; additional *Gymnosporangium* rusts in Maine, by F. H. Steinmetz and A. E. Prince; and tobacco downy mildew, found in Indiana by P. R. Miller and in Massachusetts by O. C. Boyd.

No. 13.—Preliminary data relating to the development of wheat stem rust in 1937, by E. C. Stakman; wheat stem rust in Kansas, by L. E. Melchers; wheat stem rust in North Dakota, by W. E. Brentzel; reports of damage to wheat from scab in Pennsylvania and Ohio; reports on bacterial wilt of sweet corn in Massachusetts and New York; other reports on cereal diseases, including smut on sweet corn in New York and barley scald found in Missouri; curly top appears in Utah tomato fields, by H. L. Blood; onion downy mildew situation in New York, by A. G. Newhall; other reports on onion downy mildew (Massachusetts and New York); potato late blight in New York, by H. S. Cunningham; reports on downy mildews of various crops; vegetable diseases reported from New York; summary of tobacco downy mildew in Virginia, Tennessee, Kentucky, and Indiana this year, by P. R. Miller; report of committee of the Tobacco Research Council on the black shank disease of tobacco; southern *Scierotium* rot causing damage to sugar beets in Arizona, by J. G. Brown; spray injury to apples and peaches in Massachusetts and New York; fruit diseases in New York; some diseases reported on ornamentals; and *Cephalosporium* wilt (apparently new) of persimmon, by B. S. Crandall and R. W. Davidson.

[Plant disease work by the New Haven Station] (*Connecticut [New Haven] Sta. Bul. 393 (1937), pp. 173-181, 189*).—Reports of progress are included on virulence of chestnut blight (*Endothia parasitica*); further studies on late blight of potato and tomato; bordeaux mixture on potatoes; slip seeding of sweetpotatoes to avoid disease; sand culture of seedlings for control of damping-off; stimulation of muskmelons by sprays; yellows-resistant cabbage; "X" disease of peach; *Botrytis* rot on strawberries; spraying apples with fungicides; seed testing; plant disease survey, including notes on 142 diseases,

mostly fungus; the present status of work on the Dutch elm disease; and white pine blister rust control.

[Plant disease work at the Maryland Station] (*Maryland Sta. Rpt. 1936, p. XXXVI*).—Progress reports are included on strawberry root diseases and the life history of the peach stone fungus *Oryzospora*.

[Plant disease work at the Nebraska Station] (*Nebraska Sta. Rpt. [1936], pp. 33, 34*).—Reports of progress are given relative to a survey of the 1935 cereal rust epidemic; the bacterial blights of beans; and a preliminary account of the potato disease known among growers as "hay wire."

[Plant disease work by the Ohio Station] (*Ohio Sta. Bul. 579 (1937), pp. 34-38, 39-42, 132*).—Progress reports are included on apple scab experiments, by H. C. Young; wetting agents for sulfur, sulfur toxicity, and steam vapor spraying, all by Young and H. F. Winter; raspberry anthracnose, by Winter; fasciation of sweet peas and other plants, and potato spraying experiments, both by P. E. Tilford; the effectiveness of various copper-containing spray materials in vegetable disease control, the effect of seedbed treatments on tomato transplants, and a test of copper fungicides, stickers, and spreaders on ginseng, all by J. D. Wilson and H. A. Runnels; the Dutch elm disease, and root rot disease of elms (cause unknown), both by Tilford; sick wheat, and bacteriophage inhibiting *Ap[anobacter (=Phytomonas)] stewartii*, both by R. C. Thomas; freeing raspberry stock from gall, by Winter; further progress in the development of a new tomato variety resistant to leaf mold, and progress in the breeding of tomato varieties resistant to *Fusarium* wilt for greenhouse and canning industries, both by L. J. Alexander; and white pine blister rust control, by O. J. Dowd.

Disease relationships in grafted plants and chimaeras, T. E. T. BOND (*Biol. Rev. Cambridge Phil. Soc., 11 (1936), No. 2, pp. 269-285*).—From the studies reported it is concluded that the effects of grafting may be direct (owing to the transmission of causal agents or substances through the graft union), or indirect (due to a change in the normal responses to environal conditions). Negative results indicate that resistance and susceptibility are either genotypic properties of the protoplasm or are due to some factor not, as such, transmissible.

In artificially induced *Solanum* chimeras, tests with *Septoria lycopersici* indicated that the two components retain their characteristic reactions to infection unaltered.

Examples are given of the practical importance of grafting in the prevention and control of disease and mechanical injury in fruit and ornamental trees and shrubs. The importance of incompatibility between stock and scion is discussed, and examples are quoted in which grafting has led to the transmission of an unsuspected virus disease. The dangers from improper fitting and tying of the graft union are stressed.

The determination of physiological races of phytopathogenic fungi [trans. title], E. C. STAKMAN, M. N. LEVINE, J. J. CHRISTENSEN, and K. ISENBECK (*Nova Acta Leopoldina, n. ser., 3 (1935), No. 13, pp. 281-336, pls. 5; abs. in Minnesota Sta. Rpt. 1936, p. 19*).—The paper summarizes the methods for determining physiologic races of some of the most important plant pathogens, particularly the smuts, rusts, and diseases caused by Fungi Imperfecti of cereals. Detailed keys for the determination of physiologic forms of the rusts and smuts are given.

Fungi associated with tree cankers in Iowa.—II, *Diaporthe*, *Apioportha*, *Pseudovalsa*, and their related conidial stages, J. C. GILMAN and G. L. McNEW (*Iowa Acad. Sci. Proc., 42 (1935), p. 92*).—This abstract of a paper continuing the series (E. S. R., 75, p. 507) is a contribution from Iowa State College.

Eradication of citrus canker and control of phony peach and peach mosaic. B. M. GADDIS (*Jour. Econ. Ent.*, 29 (1936), No. 5, pp. 940-944).—This progress report on phony peach control and citrus canker eradication covers the 18-mo. period beginning July 1, 1934, and on the peach mosaic survey and control for the period beginning in August 1935. "The activities of these projects are conducted in cooperation with the several affected States, which have rendered material financial and personnel assistance."

***Aspergillus fischeri* Wehmer, a fungus mildly parasitic on a number of plants.** M. B. HARRIS (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 3, pp. 378-383, figs. 2).—As a result of the observations and experiments discussed, it is believed that *A. fischeri* can be classified as parasitic on some plants. It was found on bean, geranium, almond kernels, stem of tree peony, interior of caprifigs, heartwood of peach, almond, and apricot trees, roots of privet hedge, and twigs of Mayflower peach. Since no very extensive signs of disease were found on any plants except beans and geraniums, these hosts were the only ones experimentally studied.

Host plants of *Cuscuta glomerata*. H. L. DEAN (*Iowa Acad. Sci. Proc.*, 42 (1935), pp. 45-47).—In a previous paper⁴ the author listed 83 host species for *O. gronovii*, to which 6 additional hosts have since been added. In the present contribution 54 host species (39 genera in 22 families) are listed for *C. glomerata*. Seven of these are woody plants while the remainder are herbaceous, including 2 sedges, 6 grasses, and 1 pteridophyte.

The tolerance of *Erysiphe polygoni* and certain other powdery mildews to low humidity. C. E. YARWOOD (*Phytopathology*, 26 (1936), No. 9, pp. 845-859).—This paper reports studies conducted at Purdue University and the Universities of Wisconsin and California in cooperation with the U. S. D. A. Bureau of Plant Industry. On dry glass slides in Petri dishes with humidities controlled by graduated concentrations of sulfuric acid, conidia of *E. polygoni* from red clover and bean germinated well at 100 percent relative humidity and generally also at r. h. approaching 0, though here shriveling soon, especially at high temperatures. Several hours of predrying sometimes resulted in higher than normal germination at 100 percent r. h. The conidia of this species and of *E. graminis* shrank on germination, even at high r. h., while those of *Sclerotinia fructicola*, *Colletotrichum trifolii*, and *Cicinobolus cesatii* swelled on germination in or on water but failed to germinate on dry slides at any r. h. Infection and mycelial development of the powdery mildews on various host plants tested was but little retarded by low atmospheric or soil moisture. Rain markedly checked the normal formation and dissemination of clover mildew conidia. Even high air humidity reduced their formation.

Viability and longevity of chlamydospores of *Ustilago crameri*. C. S. WANG (*Phytopathology*, 26 (1936), No. 11, pp. 1086, 1087).—In this study by the University of Minnesota the chlamydospores germinated even before morphologically mature. Some had retained their viability for at least 62 yr.

The ultracentrifugal study of virus proteins. R. W. G. WYCKOFF (*Amer. Phil. Soc. Proc.*, 77 (1937), No. 4, pp. 455-462, pls. 3).—"An air ultracentrifuge has been developed which is giving twofold help in the study of viruses. (1) Analytical runs with it, besides furnishing a measure of the size of the virus molecules, can tell whether a preparation is pure and what may be the molecular weight of its impurities, whether a virus consists of one molecular species or a family of related proteins, etc. (2) Runs in which large volumes are ultracentrifuged in fields sufficiently great to sediment any of the known viruses

⁴ *Rhodora*, 36 (1934), No. 430, pp. 372-375.

provide the basis for a method of preparing pure virus proteins without having recourse to chemical treatment. This method opens up the way to the study of viruses which, unlike that of the tobacco-mosaic disease, are relatively unstable or present in only small amounts."

Fungicide adjustment: Preparation to meet requirements of disease and host, A. C. SESSIONS (*Indus. and Engin. Chem.*, 28 (1936), No. 3, pp. 287-290).—This paper presents the results of work conducted mostly at the New Jersey Experiment Stations. A discussion is given of the factors involved in fungicide injury and in the problem of adjusting ammoniated copper silicate combinations to provide maximum fungicidal efficiency with minimum host damage, as determined by the effects on the spores of *Pestalotia* species and on peach and apple trees. The author indicates that these studies are being continued with other hosts to determine where the compromise between safety and fungicidal efficiency lies, in order that the copper silicate composition may be prepared which may meet these requirements.

Undescribed species of Cercospora and Cercospora on certain grasses in Oregon and Washington, R. SPRAGUE (*Mycologia*, 29 (1937), No. 2, pp. 199-206, figs. 3).—In this cooperative paper by the U. S. D. A. Bureau of Plant Industry and the Oregon and Washington Experiment Stations are described *Cercospora holci* on *Holcus lanatus*, *C. subulata* on *Melica subulata*, and *Cercospora bromi* on *Bromus rigidus*, all new species and illustrated.

The susceptibility of certain wild grasses to Tilletia tritici and Tilletia levis, G. W. FISCHER (*Phytopathology*, 26 (1936), No. 9, pp. 876-886, figs. 3).—Crested wheatgrass (*Agropyron cristatum*) affected in the field with bunt or stinking smut bore a smut ball in nearly every floret. Morphologically and pathogenically this smut proved similar to certain physiologic forms of *T. tritici*. Inoculations at the Washington Experiment Station resulted in 63.1 percent bunted heads on Hybrid 128, 8.53 percent on Turkey, and less on other winter varieties, with 65 percent on Hard Federation spring wheat. Inoculations revealed the susceptibility of *A. cristatum*, *A. pauciflorum*, and *A. subsecundum* to both *T. levis* and *T. tritici*, and *Hordeum nodosum* to *T. tritici*. These grasses were susceptible to the physiologic form of *T. tritici* from *A. cristatum*, as well as to others. Evidence of considerable varietal difference was found in the susceptibility of different selections of *A. pauciflorum* and of *A. cristatum* to *T. levis* and *T. tritici*.

Experiments on the chemical control of snow-mould of turf in Alberta, W. C. BROADFOOT (*Sci. Agr.*, 16 (1936), No. 11, pp. 615-618; *Fr. abs.*, p. 618).—*Fusarium* sp., *Rhizoctonia* sp., and an unidentified basidiomycete were constantly associated with snow mold injury at Edmonton. Since isolates of each proved pathogenic at 6° C. to *Festuca rubra fallax*, it is concluded that any one or all three of these fungi, acting alone or together, may cause turf injury in Alberta.

Either calomel or mercuric chloride proved effective for control, provided not less than 4 oz. per 1,000 sq. ft. was applied. As much as 8 oz. caused no noticeable injury when the turf was lightly watered following application.

Fungus parasites of cereal rusts [trans. title], K. HASSEBRAUK (*Phytopath. Ztschr.*, 9 (1936), No. 5, pp. 513-516).—Following mention of two previously known fungi parasitic on rusts, the author reports the definite identification of *Verticillium niveostratosum* and *Cephalosporium acremonium* as parasites of *Puccinia* spp. and several other rust parasites not yet definitely determined.

A method of inoculating seed barley with black loose smut for use in studies on physiologic races, V. F. TAPKE (*Phytopathology*, 27 (1937), No. 1, pp. 115, 116).—A highly effective wet method of inoculating seed barley with the

black or seedling-infecting loose smut of barley (*Ustilago nigra*) is described. It was especially devised to eliminate the hazard of mixing smut collections, which is so troublesome in studies of physiologic races when the usual spore-dust method is used.

Echinulation of chlamydospores and the pathogenicity of a previously undescribed physiologic race of *Sphacelotheca cruenta*, H. A. RODENHISER (*Phytopathology*, 27 (1937), No. 5, pp. 643-645).—Observed under the oil-immersion objective, chlamydospores of *S. cruenta* appeared finely echinulated as compared with the smooth spores of *S. sorghi*. Evidence was obtained of segregation of factors governing the spore characters, type of sori, and color of the peridia. Chlamydospores from infected Johnson grass, collected in Arizona, had somewhat more prominent echinulations than any previously observed, and there is strong evidence that it represents a physiologic race pathogenically distinct from races 1 and 2 of Melchers (E. S. R., 70, p. 348). Pathogenicity tests indicated the susceptibility of kafir \times feterita and the resistance of Pierce kaferita to this form.

Effect of leaf-hopper yellowing upon the carotene content of alfalfa, H. W. JOHNSON (*Phytopathology*, 26 (1936), No. 11, pp. 1061-1063, fig. 1).—From the determinations reported it would appear that leafhopper-yellowed alfalfa has about one-half the carotene content of green alfalfa and is, therefore, only about one-half as rich in potential vitamin A activity.

Bean mosaics: Their relations to the canning crop, O. A. REINKING (*Canner*, 84 (1937), No. 17, p. 20).—This contribution by the New York State Experiment Station briefly summarizes the present data on symptoms, hosts, and control of common and yellow bean mosaics and of a mosaic of Wisconsin Resistant Refugee bean which is possibly new. Since only the first named is particularly destructive to canning varieties of the Refugee type, the chief control studies by the station have been directed toward combating this disease, and some of the hybrids made between the mosaic-immune Robust pea bean and the Stringless Green Pod Refugee give promise of combining desirable canning qualities with resistance. Observations in the State indicate that Wisconsin Refugee may have a place with eastern canners for a short time but that Idaho Refugee will soon replace it.

Powdery mildew (*Erysiphe polygoni*) on garden snap beans, W. D. MOORE (*Phytopathology*, 26 (1936), No. 12, pp. 1135-1144, figs. 2).—This mildew is reported as widely distributed on snap beans and in recent years to have become of considerable economic importance throughout the Southeast. It is rarely found on the spring crop but appears each year on the fall crop, fungus development usually following light rains in late September and early October.

Although all known commercial varieties are susceptible, there is wide variation in this respect. Lists are given of those which undergo light, moderate, and severe infection.

Sulfur dusts or sprays gave good control, and sulfur-lime (75-25) proved the most economical and efficient of the materials tested.

The *Fusarium* yellows disease of celery (*Apium graveolens* L. var. *dulce* D. C.), R. NELSON, G. H. COONS, and L. C. COCHRAN (*Michigan Sta. Tech. Bul.* 155 (1937), pp. 74, pls. 18).—Since first observed in 1913, *Fusarium* yellows has been destructive in Michigan districts of intensive production and has been reported from most celery-producing States, where in some sections it has caused serious losses. Two forms, distinguishable by the symptoms produced in self-blanching varieties, were found generally in Michigan celery districts. A description of the first and differential characters of the second are given, and a California form differing from the two Michigan forms is noted. The

differential methods for forms 1 and 2 include color reactions on rice, aniline dye tests, reactions to copper salts, and morphology. Only minor morphological differences were noted, and it is suggested that the host relationship has a value equal to morphology for classifying the parasitic members of the section *Elegans*. Form 1 is made the type species *F. apii* n. sp., with form 2 a variety, *F. apii pallidum* n. v. The histological effects of the disease are those common to other fusarial wilt diseases, and besides vascular mycosis they include a pronounced tracheal gummosis and tracheal bacteriosis in field plants. The etiological relationship was proved by numerous successful inoculation tests, and each isolate induced a single form of the disease which was constant through repeated passages. The optimum for growth of *F. apii* was 28°–29° C. and for *F. apii pallidum* 26°–28°. Celery grew best at a soil temperature of 20°, and the disease was most active at 26°–30°. Observations indicated that dry soil is apparently unfavorable for yellows development, but the temperature and moisture relations are inseparable in the field. Thus if soils contain enough moisture for rapid growth they do not become hot enough to check growth, and optimum temperatures for development of the disease seldom occur.

Exclusion of the pathogen from noninfested soils is the first recommendation for control. Eradication tests (1914–15) proved the ineffectiveness of chemical treatments but demonstrated the effectiveness of steaming. Certain cultural practices as palliatives are recommended. A resistant strain of Golden Self-Blanching was developed from a 1919 selection and the Curly Leaf Easy-Blanching (a resistant green variety) from a selection of Newark Market. Michigan Golden, developed from the tall strain of Golden Self-Blanching, proved a very desirable, highly resistant type. Comparative tests (1933–34) of this with commercial yellow and green celeries are described.

Sterilization of corn grains with sodium hypochlorite, R. E. GIBSON (*Plant Physiol.*, 11 (1936), No. 3, pp. 635–639, figs. 4).—In this contribution by Purdue University, “increasing the length of time of treatment of corn grains with sodium hypochlorite solution from 0.5 to 5 hr. reduced germination somewhat, whereas it greatly decreased the percentage of infected seed. When sterilization with the disinfecting solution for an intermediate period of time was accompanied by a suction injection treatment, there was a marked reduction in the number of infected grains.”

Histological and cytological studies of ethyl mercury phosphate poisoning in corn seedlings, J. E. SASS (*Phytopathology*, 27 (1937), No. 1, pp. 95–99, figs. 2).—In ethyl mercury phosphate poisoning the leaf primordia became much thickened and developed irregular crenations and lobes, and in them and the apical meristem of the plumule cell division was inhibited and the existing cells underwent very great enlargement. Cells of the hypertrophied tissues became multinucleate, the nuclei ranging in size from minute “micronuclei” to very large “giant nuclei” (the latter polyploid). The multinucleate condition and the formation of micronuclei and giant nuclei are ascribed to the abnormal, incomplete mitosis.

Influence of “rust” on quality and yield of cotton and the relation of potash applications to control, J. H. MOORE and W. H. RANKIN (*North Carolina Sta. Bul.* 308 (1937), pp. 18, figs. 8).—“In recent years the condition known as cotton ‘rust’ has been responsible for severe damage to the quality and yield of cotton produced in the peanut area of the State. The usual fertilizer and cropping practice does not correct the condition. The application of additional quantities of potash has increased the yield and improved the quality of cotton grown on fields subject to rust damage. Results of these

and other experiments indicate that the problem may involve factors other than potash, and, therefore, further work is being planned to determine other causes and means of control."

Potash for cotton wilt in the Mississippi Delta region, L. E. MILES (*Better Crops With Plant Food*, 20 (1936), No. 12, pp. 18-22, 41-44, figs. 2).—In the rather heavy soils typical of the Yazoo-Mississippi Delta the wilt due to *Fusarium vasinfectum* is usually of minor importance, but local areas occur in which the soils are more favorable to the fungus. The situation in the Delta is further complicated by the presence of a second wilt due to *Verticillium dahliae*, which causes similar symptoms but is more common on the heavier soils.

The tests here reported as a contribution from the Mississippi Experiment Station were concerned with the *Fusarium* type of wilt, and the results were confirmatory of the benefits obtained in other parts of the State (E. S. R., 76, p. 201) by the application of adequate amounts of potash in connection with the use of cotton varieties of at least moderate resistance.

Pea seed treatment, K. J. KADOW (*Canning Trade*, 59 (1937), No. 29, p. 19).—As a result of trials by the Illinois Experiment Station, soil sterilization is recommended for the control of damping-off and seed treatment with copper or zinc preparations for other pea diseases.

How to apply red copper oxide and graphite to pea seed, J. G. HORSFALL (*Canner*, 84 (1937), No. 18, pp. 13, 14).—In this study by the New York State Experiment Station it was found necessary to polish the red copper oxide treated seed with graphite to insure proper drilling. To do this effectively and on a commercial scale a large drum of galvanized iron and a pea-washing reel provided with paddles were developed and are here described with full directions for use.

Some preliminary notes on the effect of psyllid yellows on seed stock from infected plants, C. H. METZGER (*Amer. Potato Jour.*, 13 (1936), No. 10, pp. 277-285).—It is concluded from this study at Colorado State College that "sufficient evidence has already been presented to show that damage to seed from psyllid infestation may occur under certain environmental conditions, and that it is dangerous to certify fields showing more than 15 percent of mild symptoms of psyllid yellows on second inspection. This tolerance was adopted in Colorado beginning with the season of 1934."

Purple top disease linked with hair-sprout tubers, H. D. LONG (*Iowa State Hort. Soc. Rpt.*, 70 (1935), pp. 314-316, fig. 1).—The author claims to have definitely linked purpletop with hair-sprout tubers, but the exact relation and cause of the trouble remain to be determined. Early strains of potato appeared to be less susceptible. The chief characteristics are described and illustrated.

Sclerotial formation in *Rhizoctonia solani* as affected by nutritional and other factors, W. B. ALLINGTON (*Phytopathology*, 26 (1936), No. 9, pp. 831-844, fig. 1).—The effect of certain nutritional factors, temperature, and H-ion concentration upon sclerotial development was studied at the University of Nebraska in cultures of a single isolate from potato. Sclerotia never formed before all the agar in the culture dish had been covered by the colony. Living potato tubers in culture dishes or soil appeared to afford nutrients necessary for sclerotia. Relatively low carbohydrate and high nitrogen favored sclerotia, which varied greatly in number and size with different nitrogen sources. Mycelial growth and sclerotium formation were best near pH 7.

Primary infection of *Setaria italica* (L.) Beauv. by *Sclerospora graminicola* (Sacc.) Schroeter, E. S. McDONOUGH (*Phytopathology*, 27 (1937), No. 3, pp. 311-313, figs. 2).—The germ tube produced by the oospore of *S. graminicola*

was found to penetrate directly into the epidermal cell of the *Setaria* seedling. The normal path of the mycelium is described as extending from the coleorhiza or primary root to the embryonic stem tip, from which it spreads to the young leaves and branches.

Effects of sulphur deficiency on the growth and metabolism of the soy bean. S. V. ELATON (*Ill. State Acad. Sci. Trans.*, 28 (1935), No. 2, p. 88).—In the sulfur deficiency tests reported the chief symptoms were the yellow-green color of the leaves, the smaller leaflets, and the thinner stems. The tops were stunted more than the roots, and the upper leaves yellowed first. These symptoms are believed to be due both to the lack of sulfur and to the poor nitrate assimilation.

Notes on the present situation with regard to diseases of sugarcane in Puerto Rico [trans. title], J. H. JENSEN (*Rev. Agr. Puerto Rico*, 28 (1936), No. 1, pp. 89-94).—In this contribution by the Puerto Rico Experiment Station, notes are presented on mosaic; gummosis; spot diseases due to *Leptosphaeria sacchari*, *Helminthosporium ocellum*, *H. stenospilum*, and *Phytomonas rubrilineans* [= *Bacterium rubrilineans*]; rots due to *Plasmodiophora vascularum* and *Colletotrichum falcatum*; the "pokkah boeng" disease due to *Fusarium moniliforme*; chlorotic stripe disease; manganese deficiency; and diseases not yet reported in Puerto Rico and methods for their exclusion.

A hypothesis to explain brown root-rot of Havana seed tobacco. A. B. BEAUMONT (*Science*, 84 (1936), No. 2173, pp. 182, 183).—As a result of work by the author (and his associates) while at the Massachusetts Experiment Station, it appears probable that the unoxidized forms of nitrogen resulting from the decomposition of organic matter are indirectly the cause of brown root rot. Because of its ephemeral and transitory character and its relation to the cropping system, it also appears that the unoxidized forms of nitrogen concerned originate from plant residues and possibly also from inorganic nitrogenous fertilizers supplied in large amounts in tobacco culture. Finally, it appears that the root rotting is due to the comparatively high concentrations of nitrogen in the roots, or a narrowed carbon-nitrogen ratio, caused by rapid absorption of basic nitrogen.

Some biochemical investigations on the crystalline tobacco-mosaic virus proteins. W. M. STANLEY (*Amer. Phil. Soc. Proc.*, 77 (1937), No. 4, pp. 447-453, pl. 1).—This abstract summarizes biochemical and serological studies of these virus proteins, with special reference to the author's own work and culminating in the following statement: "It is felt that the results fully justify the conclusion, for the present at least, that this unusual, high molecular weight protein is actually tobacco-mosaic virus."

Mosaic disease of tobacco: Action of proteoclastic enzymes on the virus fraction—nature of the virus fraction from various species of plants. A. F. ROSS and C. G. VINSON (*Missouri Sta. Res. Bul* 258 (1937), pp. 19).—The data obtained indicated the virus inactivation by trypsin to be due to adsorption rather than to enzyme action on the host. Inactivation was greatest under conditions most favorable to adsorption. Pepsin inactivated the virus at pH 3, while comparable control preparations were not inactivated as shown by inoculation into *Nicotiana tabacum*. Pepsin inactivated the virus slowly, causing a gradual reduction in infectivity. Papain alone inactivated the virus to a marked degree, and when KCN was added as an activator complete inactivation was hastened. The virus was slowly inactivated by micro-organisms.

A method of purification is described that greatly reduces the ash content of the final preparations, which are believed to be as pure as or purer than any previously described. Purified preparations from several plant species all contained about 16 percent nitrogen and 1 percent ash (calculated on the total-

solids basis). The purified virus preparations from 19 plant species, varying widely in nature, all contained nitrogen, and its content was correlated with the infectivity. It is concluded that the virus is either a simple protein or is closely associated with simple proteins.

Tomato seed treatment, R. W. SAMSON (*Canning Age*, 18 (1937), No. 5, p. 189).—Studies by the Indiana Experiment Station indicate that with effective roguing and sorting processes, together with proper selection of seed fields in the first place, seeds internally infected with tomato pathogens are eliminated, and that scalding of the fruits and thorough washing of the seeds greatly reduces the surface load. For destruction of the organisms still remaining on the surface, with a fungicidal residue left for the prevention of recontamination, some of the organic mercurials were found to offer considerable promise. Ethyl mercury tartrate proved particularly effective in the tests reported, but the performance of the treated seeds under varied conditions must be determined before the method can be recommended for general use.

A spray program for greenhouse tomatoes, J. G. HORSFALL (*Canner*, 84 (1937), No. 16, pp. 9, 10, fig. 1).—This contribution from the New York State Station outlines a program found successful in controlling diseases of greenhouse tomatoes, involving the dusting of seeds and spraying of the soil and plants with red copper oxide. On account of injury to the tender leaves of seedlings by the lime in bordeaux mixture and copper-lime dust, these preparations should not be used.

The treatment of glasshouse soils with chloropicrin for the control of *Heterodera marioni* (Cornu) Goodey, and other soil pathogens, W. NEWTON, J. E. BOSHER, and R. J. HASTINGS (*Canad. Jour. Res.*, 15 (1937), No. 5, Sect. C, pp. 182-186).—"Chloropicrin in 1-cc doses is lethal to bulb nematodes at 6 in. from the point of injection or within a soil volume of 1 cu. ft. It is also lethal to fungi. The vegetative stages are destroyed at 1:195,000 and certain sclerotia at 1:90,000. The injection of chloropicrin into greenhouse soils lowered the incidence and pathogenicity of a root knot infection on both a summer and winter crop of tomatoes and greatly increased the yields of fruit."

Turnip brown heart, R. R. HURST and D. J. MACLEOD (*Sci. Agr.*, 17 (1936), No. 4, pp. 209-214, figs. 4; *Fr. abs.*, p. 214).—Brown heart may occur in very small turnips but is most commonly found in roots greater than 2 in. in diameter. The symptoms are described.

"Tests conducted over a period of 3 yr. in the Maritime Provinces demonstrated that turnips require boron for normal development, and further that the addition of this element to the land is a safeguard against brown heart. Finely powdered borax has been the most satisfactory source of boron for this purpose, 15 to 20 lb. per acre giving highly satisfactory control without causing injury to ordinary crops in subsequent rotations. Heavy liming of the soil predisposes the turnip to brown heart, while naturally alkaline soils render borax less effective. Proven methods of applying borax are as follows: In the drill, at the sides of the drills, broadcast, [and] combined with the fertilizer and dispersed by means of ordinary machine spreaders. The general inclusion of borax with commercial turnip fertilizer is not recommended at present."

Fruit and vegetable diseases on the Chicago market in 1936, G. B. RAMSEY (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1937, Sup. 101, pp. 81-96).—Data are presented on the receipts by railroad and truck in the Chicago area, but the main space is devoted to notes on the diseases found affecting some 36 fruits and vegetables, listed alphabetically by common names.

The fungous flora of normal apples, G. A. HUBER (*Wash. State Col., Res. Studies*, 3 (1935), No. 1, pp. 26-28).—This is an abstract of a dissertation from the State College of Washington, dealing with the sources of contamination and

spore load and with the fungi present and their relation to decay. Over 20 species of 14 genera, not previously reported on apples in the State, were obtained, and the following are demonstrated for the first time as capable of causing decay in apples: *Sporonia* sp., *Pyrenochaeta* sp., *Chaetomella* sp., *Aspergillus* sp., *Verticillium* sp. (forms 1, 2, and 3), and *Podosporiella* spp. (Nos. 1 and 2).

Physiological disorders of apples, H. HILL and M. B. DAVIS (*Sci. Agr.*, 17 (1936), No. 4, pp. 199-208, figs. 12; *Fr. abs.*, p. 208).—From observations and studies over a 5-yr. period, no correlation was established between the amount of root injury and the occurrence of cork or internal cork, corky core, and tree or bitter pit. The conditions found associated with these disorders were high carbonate lime soils; high percentage of nitrogen and organic matter, especially along with shallow-rooted trees brought about by compact subsoils; soil moisture excesses or deficiencies coupled with a high percentage of nitrogen and organic matter; and low available potash and a high phosphorus:potassium ratio, especially in the lower soil horizons.

Boron applications, fed as a nutrient solution to potted trees or injected into trees in the solid form in the orchard, gave evidence that this element exercises a control of these disorders.

'Tree injections with boron and other materials as a control for drought spot and corky core of apple, H. R. McLARTY (*Sci. Agr.*, 16 (1936), No. 12, pp. 625-683, fig. 1; *Fr. abs.*, p. 633).—From 1932 to 1935, 30 chemicals, alone and in various combinations, were tested. Significant controls of both troubles were obtained with boric acid and manganous borate, alone or in various combinations. When more than 0.48 g of BO_3 was used per 100 sq. cm of trunk cross-sectioned area no drought spot occurred in the next season's crop, and when more than 1.83 g were used there was no corky core. No foliage injury was noted with amounts of BO_3 up to 5.92 g, though slight injury occurred at the points of injection.

The connection between *Dematophora necatrix* and *Rosellinia necatrix*, H. N. HANSEN, HAROLD E. THOMAS, and H. EARL THOMAS (*Hilgardia [California Sta.]*, 10 (1937), No. 14, pp. 559-565, pl. 1).—Continuing the study of this fungus, previously found to be highly destructive to apple roots in the State (E. S. R., 72, p. 633), mature perithecia were developed on infected root samples held in damp chambers and identified as belonging to *R. necatrix*. "The germination of ascospores, with subsequent production in culture of the conidial stage and the demonstration of pathogenicity, are considered to constitute adequate proof of the genetic relation of *D. necatrix* to *R. necatrix*." A pycnidial fungus of the form genus *Phomopsis* and *R. aquila* (?) were found associated with the pathogen under study.

Rootstocks in relation to the black root rot (*Xylaria mali*) of apple trees, F. J. SCHNEIDERHAN (*Va. State Hort. Soc. Rpt.*, 41 (1936), pp. 69-74).—This contribution by the West Virginia Experiment Station briefly summarizes our knowledge on this disease and presents data on approximately 2,000 inoculations on 75 known rootstocks, 631 seedlings, and 46 species of forest trees. None of the rootstocks thus far tested proved immune.

Apple mosaic, H. EARL THOMAS (*Hilgardia [California Sta.]*, 10 (1937), No. 14, pp. 579-588, figs. 3).—An apple mosaic, found in California and apparently identical with the one known in the East, was transmitted by grafting to *Cotoneaster harroviana*, *Eriobotrya japonica* (loquat), *Photinia arbutifolia* (toyon), *Rosa* sp. (varieties Belle of Portugal and Independence Day), and *Sorbus pallescens*. Heating dormant apple shoots, in several ways to near the killing point of apple tissues failed to inactivate the virus.

Some effects of the environment on the spongy dry rot of apples, S. DIACHUN (*Phytopathology*, 27 (1937), No. 2, pp. 203-206).—Observations on several varieties of apples artificially inoculated with *Colletotrichum fructus* indicated that spongy dry rot may resemble ordinary black rot when the formation of setose acervuli is inhibited by low atmospheric humidity. Leaves of apple seedlings artificially inoculated became infected at high atmospheric humidity, and abundant acervuli were formed.

Incidence and development of apple scab on fruit during the late summer and while in storage, C. O. BRATLEY (*U. S. Dept. Agr., Tech. Bul. 563* (1937), pp. 46, figs. 14).—Controversies regarding the responsibility for the apparent increase of scab in storage furnished the original instigation for this research. *Venturia inaequalis* was found to grow at 32° F., the usual storage temperature advised for apples. During early summer, enlargement of the lesions was similar to that of equal areas on the fruit, but later the lesion enlargement greatly outstripped that of the fruit. In commercial storage only a small percentage of old lesions enlarged, but the number of new lesions varied with the season and source of fruit, at times becoming commercially important. The greatest lesion enlargement occurred on fruit packed wet in tight boxes, while in open containers there was more shriveling and often a decrease in lesion size. More new lesions usually occurred on fruit from poorly sprayed, heavily infected trees, and on unsprayed fruit the number appeared to be correlated with the amount of foliage on the tree. A week's delay in storing produced no consistent effects. With constant relative humidity, greater enlargement of lesions occurred at 40° than at 32°, but fluctuations between these extremes were without apparent effect. With constant temperature, higher humidities promoted lesion enlargement. Small differences in temperature and humidity had little effect on the number of new lesions, but higher differences often induced an earlier development in storage. Lesions may appear at any time during storage. More lesions appeared on scabby than on clean fruit from the same tree. From spontaneous infection more new lesions appeared on the stem half of the fruit, though inoculation tests showed no such difference. Successful inoculations were equal on blush or green areas. No macroscopic differences indicating lesions which would later enlarge were observed, and generally there was no appreciable difference between lesions that had enlarged in storage and those that had not. Although usually darker, lesions appearing on McIntosh fruit during storage were often quite like orchard lesions. Similar lesions also occurred (1933) on Baldwin fruit.

Apples were successfully inoculated throughout their development and even after picking, but not at maturity if stored immediately thereafter. Scab did not spread from diseased to clean fruit, indicating that new lesions during storage result from infection on the tree. The length of the wet period necessary for fruit infection proved to be much longer than that reported for foliage and to increase as the fruit developed. The shortest latent period of infection observed on inoculated fruit was 23 days, and the longest 6½ mo. In bagging experiments over 3 yr. the latest spontaneous infection occurred about mid-August, and some of the resultant infection appeared after the fruit was stored.

Will heat and dry weather kill the apple scab fungus, H. W. ANDERSON (*Ill. Hort.*, 25 (1936), No. 4, p. [1]).—In this contribution by the University of Illinois, evidence is presented from two seasons with extreme droughts (1934, 1936), indicating the improbability that heat and drought can eradicate scab where it has become established in the spring. Observations emphasize the value of adequate spraying.

Non-parasitic disease of the apple in storage, H. H. PLAGGE, T. J. MANEY, and B. S. PICKETT (*Amer. Pomol. Soc. Proc.*, 51 (1935), pp. 181-192, figs. 2).—This contribution by the Iowa Experiment Station comprises a general account summarizing the results of 12 yr. of study of types of break-down, scald, Jonathan spot, water core, brown heart, bitter pit, and other diseases sometimes confused (freezing injury, cork and drought spot, and internal browning), together with data on storage temperatures for apples.

Fusarium lateritium v. *fructigenum* in relation to wilt of China aster, R. S. RIKER (*Phytopathology*, 26 (1936), No. 11, pp. 1085, 1086).—In this note from the University of Wisconsin, the author questions the pathogenicity of this fungus for China-asters, as reported by Riker and Jones (*El. S. R.*, 74, p. 60). Recent examinations of their strain suggest that it was a mixture with *F. conglutinans callistephi*, and that the infections were due to the latter.

A bacterial disease of *Delphinium ajacis*, B. O. DODGE (*Jour. N. Y. Bot. Gard.*, 36 (1935), No. 431, pp. 257-260, figs. 2).—This is a preliminary note on a bacterial disease found very destructive to *D. ajacis* at The New York Botanical Garden, and which was apparently arrested by spraying with bordeaux mixture.

A bacterial leaf spot of *Geranium*, W. H. BURKHOLDER (*Phytopathology*, 27 (1937), No. 4, pp. 554-560, fig. 1).—A bacterial leaf spot of *G. sanguineum*, prevalent about Ithaca, N. Y., and apparently new, is described. The causal organism (*Phytomonas gerani* n. sp.) was isolated, its pathogenicity proved, and an extensive description is given. It is pathogenic also for *G. maculatum*, *G. pratense*, and *G. sylvaticum*. Infection was not obtained on *Pelargonium hortorum*. The fungus overwinters in lesions on the leaves of *G. sanguineum*.

The nematode disease of bulbous iris caused by *Ditylenchus dipsaci* (Kühn 1858) Filipjev 1936, and experiments on its control by bulb treatment, W. NEWTON, R. J. HASTINGS, and J. E. BOSHER (*Canad. Jour. Res.*, 15 (1937), No. 5, Sect. C, pp. 175-181, fig. 1).—"The individual bulbs that arise from a nematode-infested mother bulb are seldom all infested, which is accounted for by the disappearance of the old bulb when the daughter bulbs form, necessitating a re-entrance. The nematodes appear to attack the stem and tunics first. Normally they enter the bulb proper through the base. Tip infection occurs, but is comparatively rare. No evidence has been obtained that nematodes enter the plants above soil level. Basal discoloration, as revealed by the removal of the dry caps from the bulb bases, is suggested as a diagnostic symptom in addition to the characteristic streaks in the outer fleshy scale and the discoloration at the base of the stems. Death and chlorosis of iris plants could not be attributed to bulb nematodes in infested plantations. No evidence was obtained that the bulb nematode significantly affects the forcing capabilities of iris bulbs.

"Immersion in water for 1 hr. at 44° C. killed iris bulbs when done early in November, with or without disinfectants. Treatments of iris bulbs with cold organic mercury solutions and other solutions increased the yield of bulbs, apparently because they controlled *Penicillium* sp. and other parasites rather than bulb nematodes. Fumigation with ethylene dichloride and ethyl acetate injured iris bulbs and failed to control the nematodes. Formalin as a fumigant was less injurious, but it was not effective as a nematocide."

Bacterial leaf spot of *Primula*, P. A. ARK and M. W. GARDNER (*Phytopathology*, 26 (1936), No. 11, pp. 1050-1055, fig. 1).—The bacterial leaf spot of *Primula* is characterized by brown spots with yellow borders on the older leaves. In this study by the University of California, *Phytomonas primulae* n. sp. was shown to be the cause and is described. Colonies on agar media be-

come green in color. The organism grows well at the low temperatures favorable to *Primula*.

Among 27 species and varieties inoculated, 21 proved susceptible. Spontaneous infection has been noted on 5 species, 1 of which was not included in the inoculation tests. In inoculation tests and in the garden only the older leaves proved susceptible.

Red copper oxide as a rose-spray, J. G. HORSFALL (*Amer. Rose Ann.*, 1936, pp. 117-120).—This contribution by the New York State Experiment Station reports progress in tests and general experience with this fungicide, including a list of rose varieties the leaves of which were injured by it. Its fungicidal properties are satisfactory, and attempts are being made to reduce its injuriousness.

Physiologic races of snapdragon rust, C. E. YARWOOD (*Phytopathology*, 27 (1937), No. 1, pp. 113-115, fig. 1).—Two physiologic races of *Puccinia antirrhini* were distinguished by cross-inoculations on detached leaves. Race 1 attacks commercial, rust-susceptible snapdragons but not the recently developed rust-resistant strains. Race 2, found in five coastal districts of California, attacks severely all the susceptible and resistant varieties tested.

Balloons as indicators of insect drift and of Dutch elm disease spread, E. P. FELT (*Bartlett Res. Labs. Bul.* 2 (1937), pp. 3-10, fig. 1).—"These records in connection with the justified assumption that most of the diseased elms in the northeastern United States were infected by beetles which must have issued from or fed upon diseased trees warrant the belief that the somewhat distant spread of the trouble in the Northeast is due to wind drift. Incidentally, this in connection with the marked southeastward drift of balloons along the south shore of New England, suggests a reason for the relatively slow progress of the elm bark beetle toward a more eastern area extending out from Cambridge, Mass., where this insect has been known to occur from an earlier and independent introduction which was discovered about 1909."

A Verticillium root disease of American elm, L. R. TEHON and H. L. JACOBS (*Davey Inst. Tree Surg. [Kent, Ohio] Bul.* 6 (1936), pp. 32, pls. 2, figs. 18).—This disease is reported to have been known for some years prior to 1927 in the Ohio Valley and to have been especially destructive to shade trees in Cincinnati and Dayton. The symptoms are described, and the disease is shown to be due to *V. rhizophagum* n. sp. It is essentially a parasitization and destruction of the most recently formed xylem, of the cambium, and of the newest phloem. The host-parasite relations are discussed in detail. Attempted treatment on trees in the preliminary stages of the disease has thus far proved futile.

A bacterial gall disease of Douglas fir, *Pseudotsuga taxifolia*, H. N. HANSEN and R. E. SMITH (*Hilgardia [California Sta.]*, 10 (1937), No. 14, pp. 567-577, figs. 4).—A gall disease of the twigs and stems of Douglas fir is described and shown to be due to *Bacterium pseudotsugae* n. sp. Actual contact of the pathogen with xylem elements appears essential for host infection, and *Chermes cooleyi* is suggested as the probable insect carrier. A species of hemlock, three of pine, and several herbaceous plants were inoculated, with negative results.

A new species of Chondropodium on Pseudotsuga taxifolia, W. L. WHITE (*Mycologia*, 28 (1936), No. 5, pp. 433-438, figs. 7).—This study by Cornell University reports *C. pseudotsugae* n. sp. (illustrated and described) as causing a common but not serious disease of the outer cortex.

A leaf and twig disease of hemlock caused by a new species of Rosellinia, G. H. HEPTING and R. W. DAVIDSON (*Phytopathology*, 27 (1937), No. 3, pp. 305-310, figs. 2).—A disease causing local damage to hemlock in North Carolina was

shown to be due to *R. herpotrichioides* n. sp., which is fully described. The fungus occurs as a cobwebby to felty growth over twigs and leaf bases and results in death of affected parts. Perithecia are produced on this superficial mycelium.

The death of larch trees [trans. title], E. MÜNCH (*Forstwiss. Centbl.*, 58 (1936), Nos. 14, pp. 469-494, figs. 8; 16, pp. 537-562, figs. 4; 17, pp. 581-590).—The history and literature of the larch disease are comprehensively reviewed (including the various causes to which it has been ascribed and a critique of previous theories), and the symptoms are described in detail. The author then gives a full discussion of his own comprehensive investigations and observations, including experiments relative to the influences of frost injuries, cankers, and the canker fungus *Peziza willkommii* [= *Dasyscypha calycina* or *D. willkommii*], the drying up of twigs and branches, lichens, the ascending character of the malady, and various other predisposing and aggravating causes (type of stand, insect injuries, leaf fungi, the recuperative powers of the trees under various conditions, soils, etc.).

It is concluded that the primary factors under German climatic conditions lie in the frost susceptibility of the opening buds and cambial growth in early spring, which allows the canker fungus to gain a foothold. Various other contributory factors enumerated also doubtless aid the fungus in assuming a parasitic or even epidemic role.

Larch canker, G. G. HAHN (*Natl. Shade Tree Conf. Proc.*, 12 (1936), pp. 120-127).—The author reports a heavy infection of imported larch trees in Massachusetts (1927), identified as the true European larch canker and observed in the United States for the first time. Details are given regarding the susceptible species, the species reported as attacked in Europe and America, the world distribution, the source of the disease and its introduction into the United States, the economic importance and control of the disease in Europe, and the reason for attempted eradication in the United States.

The cultural characters and pathogenicity of the casual fungus *Dasyscypha willkommii* are compared with related forms. Only living healthy larch species were successfully infected by the larch canker fungus, whereas the related *D. calycina* and native forms were unable to infect larch under conditions of artificial inoculation.

The European larch canker and its relation to certain other cankers of conifers in the United States, G. G. HAHN and T. T. AYERS (*Jour. Forestry*, 34 (1936), No. 10, pp. 898-908, figs. 4).—An intensive search for this canker (*Dasyscypha willkommii*), discovered in 1927 on imported *Larix europaea* from Great Britain, has shown it confined to a small area in Massachusetts. The fungus is distinct from the imported saprophyte *D. calycina*, and infects only species of *Larix* and *Pseudotsuga*. Native species of the fungus genus on other hosts are discussed.

A general spread of this disease in the United States has apparently been averted by prompt action in the destruction of the original focus of infection, but new infections found in 1935 demonstrate that periodical reexaminations of the infested area are necessary to complete eradication.

Present knowledge on the disease is briefly reviewed, and a bibliography of 21 titles is included.

Blister-rust control: Manual for field men—Northeastern States, compiled by C. C. PERRY ([Boston], 1936, 5. ed., rev., pp. [2]+82, [pls. 12]).—This manual, prepared in cooperation with the U. S. D. A. Bureau of Entomology and Plant Quarantine, attempts to "touch briefly and simply upon the more important subjects that may be met with in connection with the field work" on white pine blister rust, with special reference to the Northeastern States.

The progress of blister rust in planted northern white pine, R. R. HIER (*Jour. Forestry*, 34 (1936), No. 5, pp. 506-511, fig. 1).—Among 1,560 young trees of white pine (*Pinus strobus*) 3 yr. old from seed, planted in 1927 in an area at Warrensburg, N. Y., protected from subsequent infection by white pine blister rust (*Cronartium ribicola*) by maintenance of a *Ribes*-free condition, 244 were already infected when set out. Of these, 131 died in the next 8 yr., while 113 remained alive in 1935, 73 of which had outgrown all signs of rust. Of the 1,316 trees that were uninfected when set out, 190 had died, all from causes other than the rust. With the protection afforded by the absence of *Ribes* within 700 ft. of the planting, no new rust infections developed at any time, and the amount of aeciospore production was progressively reduced by the gradual death of the initially infected trees.

A method of separating the teliospores of *Cronartium ribicola*, R. K. PEARSON (*Phytopathology*, 26 (1936), No. 9, pp. 923-925, fig. 1).—When fragments of leaves bearing the telia of *C. ribicola* were heated in 1-N nitric acid the telial columns were quickly detached and easily broken down by pressure on the cover glass into single teliospores, facilitating rapid counts.

Immunity of Viking red currant from white pine blister rust under field conditions, G. G. HAHN (*Phytopathology*, 26 (1936), No. 9, pp. 860-875, figs. 2).—The resistance (near immunity) of Viking currant (Syn. Rød Hollandsk Druerips) from eastern and western strains of *Cronartium ribicola* was shown for 973 bushes amply exposed for 3 yr. (1932-34) to natural infection in 28 plats distributed through blister rust areas in New England, New York, Oregon, and Ontario. Artificial inoculations of test plants with aeciospores of blister rust under favorable atmospheric conditions failed. These results, with others already reported (E. S. R., 73, p. 65), indicate a high resistance to North American and British strains of the rust, and confirm Norwegian observations. That resistance is a dominant character was evidenced by preliminary greenhouse tests.

Some results of investigations on *Polyporus schweinitzii* Fr., H. H. YORK, R. E. WEAN, and T. W. CHILDS (*Science*, 84 (1936), No. 2172, pp. 160, 161).—*P. schweinitzii* was found causing serious root and butt rot in plantings of white pine (*Pinus strobus*) in western New York, but was not connected with a resinosis of this host most troublesome in soil with pH 6.0 or above in the same State.

Variability of *Polyporus schweinitzii* in culture, T. W. CHILDS (*Phytopathology*, 27 (1937), No. 1, pp. 29-50, figs. 3).—Fifty cultures of this fungus from various hosts and localities differed rather widely in appearance, growth rate, production of sporophores, reaction to acidity, and ability to attack wood. Differences also occurred between monosporous mycelia from basidiospores produced in pure cultures. Since no local or host-specialized strains were found, the serious damage by this fungus to planted white pine near Springwater, N. Y., is ascribed to site conditions rather than to any unusual virulence of the fungus. Comparable results reported for other fungi indicate that intraspecific variability should be given careful consideration in mycological research.

The Tympanis canker of red pine, J. R. HANSBROUGH (*Yale Univ. School Forestry Bul.* 43 (1936), pp. IX+58, pls. 12, figs. 3).—This doctoral dissertation discusses this recently found canker disease (E. S. R., 73, p. 502), damaging to *Pinus resinosa* but inconsequential on *P. strobus*, reported from Michigan, Ohio, New York, Connecticut, Rhode Island, Pennsylvania, New Jersey, Maryland, Massachusetts, and Maine and caused by a hitherto undescribed species

of *Tympanis*, previously referred to *T. pinastri*. The disease is described and illustrated. The parasitism of the fungus was demonstrated by inoculation tests. Infection was found to take place through dead laterals, spreading up to 3 ft. in a year. It was found only south of the optimum range for red pine and was more severe in pure stands than mixed and on poor sites than good, being favored by drought and poor vigor. Mixed planting, 8-ft. spacing, and judicious pruning and thinning are suggested to reduce infection.

The relation between penetration and decay in creosoted southern pine poles, R. H. COLLEY and C. H. AMADON (*Bell Tel. System, Tech. Pubs., Tel. Equip. Monog. B-937* [1936], pp. 17, figs. 9).—The detailed results of an increment borer study of over 3,000 creosoted southern pine poles standing for various periods up to 26 yr. in Florida, North and South Carolina, Tennessee, Virginia, Illinois, Wisconsin, Michigan, and New Jersey showed internal sapwood decay only in those instances where the creosote had failed to penetrate 75 percent of the thickness of the sapwood.

Intumescences on poplar leaves.—III, The role of plant growth hormones in their production, C. D. LA RUE (*Amer. Jour. Bot.*, 23 (1936), No. 8, pp. 520–524).—Intumescences were produced on leaves of *Populus grandidentata* by applying pieces of already affected leaves, crushed intumescences, ether extracts of intumescence-bearing leaves, extract of *Rhizopus suinus*, and β -indolylacetic acid, suggesting that plant growth hormones may cause intumescences on leaves in unventilated damp chambers.

Diseases and pests of the rubber tree, A. SHARPLES (London: Macmillan & Co., 1936, pp. XVII+480, pls. [5], figs. [80]).—The three main parts of this compendium deal, respectively, with general remarks on plant diseases, structure, reproduction, and physiology of fungi; form and function; and diseases and pests. The bulk of the work under part 3 groups the subject matter under root diseases; tapping panel affections; stem diseases; leaf diseases; scorching and after-effects (and miscellaneous); insect, animal, and other pests; and treatment of diseases. A discussion of forestry methods of cultivation, a list of fungi recorded on rubber trees in Malaya, a glossary, and an index complete the book.

Cytospora canker of spruces, C. J. GILGUT (*Natl. Shade Tree Conf. Proc.*, 12 (1936), pp. 113–118).—In this contribution from the Massachusetts Experiment Station the author discusses the history, distribution, symptoms, and course of this disease, shown to be due to *C. kunzei*. It is primarily a bark disease proved by artificial inoculations to enter through wounds, but the effects of the fungus are too widespread and destructive for it to be considered a weak parasite. Once established, it slowly but surely destroys the lower limbs and finally kills the tree. It is considered the most serious disease affecting Colorado blue spruce and Norway spruce in the State.

Variation in *Fomes igniarius* (L.) Gill., A. F. VERRALL (*Minnesota Sta. Tech. Bul.* 117 (1937), pp. 41, figs. 14).—This fungus, causing heart rot of many hardwood species of trees, was chosen for the present study because of its wide geographical and host ranges and because the external appearance of the fruit body and the cultural characters were already known to vary somewhat. The fruit bodies used were collected during 1931–33 from one Colorado and eight Minnesota localities. The "tissue cultures" were made by transferring small pieces of the interior of the fruit bodies to agar slants. Single-spore cultures were made by the usual procedures.

It was found that the species apparently comprises three fairly distinct groups differing in sporophore morphology, growth rate, general appearance, production of methyl salicylate odor on artificial media, rate of rotting some

wood species, and in reaction to zinc chloride. The groups did not agree with taxonomic separation into typical *igniarius* and variety *nigricans*, but were correlated with host species. Each isolate differed in some major or minor respect, except for a few that appeared to (and may) have come from the same mycelium. The differences within the groups were both morphological and physiological, but the temperature relations of all isolates on malt agar appeared to be about the same. Haploid lines grew more slowly on artificial media and rotted wood much more slowly than did the dicaryotic isolates of the parent fruit bodies. Haploid lines from the same fruit body may vary in growth rate and general appearance. No sexual fusions between the three groups were observed. New dicaryons differing in growth rate from isolates of parent fruit bodies were produced by mating lines from related fruit bodies.

The effect of certain nitrogenous compounds on the rate of decay of wood, H. SCHMITZ and F. KAUFERT (*Amer. Jour. Bot.*, 23 (1936), No. 10, pp. 635-638).—In this study at the University of Minnesota, varying amounts of asparagine and ammonium nitrate were supplied to cultures of sawdust of the heartwood and sapwood of Norway pine (*Pinus resinosa*) and paper birch (*Betula papyrifera*) and the rate of decay determined after inoculation with *Lenzites trabea* and *Polystictus versicolor*. Asparagine definitely increased the rate of decay of *Pinus resinosa* heartwood and sapwood by *L. trabea* and of *B. papyrifera* sapwood by *Polystictus versicolor* without affecting the rate of decay by the latter in birch heartwood. Except in one case where as much as 5 percent ammonium nitrate was added to *Pinus resinosa* heartwood, the addition of this material to both kinds of sapwood and heartwood failed to increase significantly the rate of decay. These results point to the probable importance of the amount and availability of organic nitrogen as a factor in determining the rate of wood decay.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Contributions on wildlife research] (*U. S. Dept. Agr., Bur. Biol. Survey, Wildlife Res. and Mangt. Leaflets BS-70* (1936), pp. 19; BS-71, pp. 6; BS-72, pp. 27; BS-73, pp. 4, fig. 1; BS-74, pp. [2], fig. 1; BS-75, pp. 2; BS-76, pp. 6; BS-77 (1937), pp. 32, pls. 2; BS-78, pp. 2; BS-79, pp. 4; BS-80, pp. [2]; BS-81, pp. 17, fig. 1; BS-82, pp. 8; BS-83, pp. 16; BS-84, pp. 9; BS-85, pp. 9, figs. 3; BS-86, pp. 4; BS-87, pp. 10; BS-88, pp. 10, pls. 4; BS-89, pp. 2; BS-90, pp. 5).—Further contributions in this series (*E. S. R.*, 76, p. 355) are as follows: Poisonous Snakes of the United States (BS-70); Wildlife in Land Planning, by W. L. McAtee (BS-71); Check-List of Marsh and Aquatic Plants of the United States, compiled by N. Hotchkiss (BS-72); Inheritance of "Woolly" in Rabbits, by A. W. Bellamy (BS-73); Nail Keg Nest Box, by G. S. Templeton (BS-74); Raising Otters in Captivity (BS-75); Some Suggestions for Bird Field Study, by M. T. Cooke (BS-76); The Wild Turkey on the Missouri Ozark Range—Preliminary Report, by H. L. Blakey (BS-77); Directions for Destroying House Mice (BS-78); Vent Diseases of Domestic Rabbits, by F. D. McKenney and J. E. Shillinger (BS-79); Feeding and Caring for Squirrels (BS-80); Suggestions for Combating Starling Roosts, by E. R. Kalmbach (BS-81); Mink Raising (BS-82); Birds in Relation to Fishes, by C. Cottam and F. M. Uhler (BS-83); Food of the Scaled Quail [*Callipepla squamata*].—Preliminary Report, by L. H. Kelso (BS-84); Self-Feeding System for Market Rabbits, by G. S. Templeton (BS-85); Sanitation in Domestic Rabbitries, by F. D. McKenney (BS-86); Some Accomplishments of the Cooperative Research Units—A Summary to January 31, 1937, by H. H. T. Jackson (BS-87); The Waterfowl Situation, 1936-37 (BS-88); and Infectious Myxomatosis of Domestic Rabbits

(Mosquito Disease, Big-Head Disease) (BS-89) and Hemorrhagic Septicemia of Domestic Rabbits (Contagious Nasal Catarrh (Snuffles), Subcutaneous Abscesses (Boils), and Other Forms) (BS-90), both by F. D. McKenney and J. E. Shillinger.

Wildlife Review, [April and July 1937] (*U. S. Dept. Agr., Bur. Biol. Survey, Wildlife Rev. Nos. 8 (1937), pp. 43; 9, pp. 40*).—A continuation of this series (E. S. R., 76, p. 651).

An animal census of two pastures and a meadow in northern New York, G. N. WOLCOTT (*Ecol. Monog.*, 7 (1937), No. 1, pp. 1-90).—In this contribution, many of the details of which are given in tables, the author reports upon a census made of two pastures and a meadow near Barneveld, in Oneida County, N. Y. A total of 6,843 invertebrates were collected from 100 sq. ft. of grasslands on Merrimac fine sandy loam between April and October 1919. The contribution is presented with a list of 42 references to the literature.

Plants eaten by California mule deer on the Los Padres National Forest, C. S. ROBINSON (*Jour. Forestry*, 35 (1937), No. 3, pp. 285-292).—A list is given of plants eaten in California by *Odocoileus hemionus californicus*, compiled from notes taken during the period 1932-35 and covering every month in the year.

What can be done to keep deer out of the orchard, O. T. MCWHORTER (*Better Fruit*, 28 (1933), No. 3, p. 8).—In the course of a brief discussion of the methods of protecting tree and other fruits from injury by deer in Oregon, mention is made of the use of a carbide automatic flash gun which operates by dripping water upon calcium carbide. The gas generated causes a loud explosion with an accompanying beam of light, every few minutes. A single gun is said to protect 1,000 young orchard trees.

Winter activity of the skunk, W. J. HAMILTON, JR. (*Ecology*, 18 (1937), No. 2, pp. 326, 327).—A study of the hibernation of *Mephitis nigra* in central New York, conducted during the winters of 1931-32 and 1933-34, is briefly reported, tabular data being given on the relative activity of male and female skunks during that period. It was found that the females are confirmed hibernators, while the males are more or less active throughout the winter. Low temperatures seemed to be the inciting cause of winter sleep.

Activity and home range of the field mouse (*Microtus pennsylvanicus pennsylvanicus* (Ord.)), W. J. HAMILTON, JR. (*Ecology*, 18 (1937), No. 2, pp. 255-263, figs. 2).—The present contribution is said to be the result of a projected study designed to analyze the dynamics of cyclic phenomena in mammals. Voles were found to be more active by day than by night, the periods of greatest activity being shortly after dawn and in the hours preceding dusk. Predation possibly plays a selective part in determining periods of greatest activity, for less activity on the part of vertebrate enemies is apparent during the early morning and late afternoon. The home range of an individual vole seldom encompasses an area in excess of $\frac{1}{15}$ acre.

The biology of microtine cycles, W. J. HAMILTON, JR. (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 10, pp. 779-790, figs. 2).—Damage caused by field mice, particularly at the height of increase in their population, of which the annual loss caused by their destruction of fruit trees, hays, cereals, and garden truck has run into millions of dollars, led to the investigation by the [New York] Cornell Experiment Station here reported. The studies reported are based chiefly on field and laboratory observations of the common field mouse (*Microtus pennsylvanicus pennsylvanicus* (Ord.)) in the Ithaca, N. Y., locality. This species exhibits variable populations, being built up in 3 or 4 yr. from a low of 15 to 40 mice per acre after the periodic decline to from 60 to 250 per acre.

"Increased population is fostered by three reproductive factors: (1) An acceleration of the breeding rate; (2) an increased number of young per litter; and (3) the lengthening of the reproductive season, which allows for greater numbers of litters per year. Causes responsible for a decrease in numbers of mice may be abiotic, such as climatic influences, or biotic, such as diseases, predators, etc. It appears that murine epizootics occurring when mice have reached the peak of their abundance are the primary causative agent reducing mouse populations. Plagues of mice are often accompanied by disease of an epidemic nature among these animals.

"Forecasting the years of mouse abundance is important, for control methods may be inaugurated before the expected period of peak population, and the extent of the damage minimized." It is concluded that future peaks may readily be forecast, but increase in mouse populations occur rapidly, so that optimum densities may be reached in 2 or 3 yr. following the decline.

Check-list of birds of the world, III, J. L. PETERS (*Cambridge: Harvard Univ. Press, 1937, vol. 3, pp. XIII+311*).—This third volume of the check list previously noted (*E. S. R.*, 72, p. 356) takes up the orders Columbiformes and Psittaciformes, the literature being covered to the close of the year 1935. A new generic and seven new varietal names are proposed.

Life histories of North American birds of prey: Order Falconiformes (part 1), A. C. BENT (*U. S. Natl. Mus. Bul. 167 (1937), pp. VIII+409, pls. 102*).—This, the tenth of a series of bulletins on the life histories of North American birds (*E. S. R.*, 68, p. 777), deals with the order Falconiformes, including vultures, kites, hawks, eagles, and American osprey.

Factors affecting yearly abundance of passerine birds, S. C. KENDEIGH and S. P. BALDWIN (*Ecol. Monog.*, 7 (1937), No. 1, pp. 91-123).—A report of a study made of the factors affecting yearly fluctuations in abundance of a typical passerine bird, the house wren (*Troglodytes aedon* Viell.), the study being made by a statistical method involving the use of coefficients of correlation.

Snow-killing of the bob-white, T. G. SCOTT (*Wilson Bul.*, 49 (1937), No. 1, pp. 21-27, figs. 3).—Observations by the extension service and experiment station of the Iowa State College, the Iowa Conservation Commission, and the U. S. D. A. Bureau of Biological Survey cooperating, here reported, have shown that reasonably healthy bobwhites may perish through imprisonment by drifting snow, that exposure to cold, high winds, and snow may kill reasonably healthy individuals, and that cover subject to drifting is not ideal. It is pointed out that research into management practices should include work upon the effect and control of drifting snow.

Bird behavior as a result of emergence of seventeen year locusts, W. J. HOWARD (*Wilson Bul.*, 49 (1937), No. 1, pp. 43, 44).—Observations of the feeding of the English sparrow, eastern robin, starling, bronzed grackle, eastern cowbird, and red-headed woodpecker on the periodical cicada near Indianapolis, Ind., are reported.

Food habits of adult pheasants in Michigan based on crop analysis method, P. L. DALKER (*Ecology*, 18 (1937), No. 2, pp. 199-219, figs. 3).—Data collected in the course of an investigation of the food habits of the pheasant from June 1930 to July 1, 1933, which centered in the general farming region of southern Michigan, are reported, the details being given in 11 tables and 3 graphs.

The introduced pheasant in Michigan is said to be a mixture of the Chinese ring-necked pheasant, the Caucasian pheasant or so-called English black-neck, and the green Japanese pheasant. It was found to be an omnivorous feeder, with the greatest variety of seeds and fruits eaten in October, when

106 plant species were represented. The high percentage of grain consumed by pheasants is not an indication of damage to grain crops, since most of it is waste, either from harvesting or planting or from manure spread on the fields. Corn, wheat, and barley comprise 83 percent of all the grain eaten. "In the pheasant territory of Michigan the most common wild seeds eaten were ragweed, yellow foxtail, skunkcabbage, and green foxtail. Ragweed accounted for 51 percent of all the seeds eaten. Wild fruits and nuts are eaten consistently, but their percentage is small (7.48), since the habitat of these species is restricted to a relatively small proportion of the pheasant range. Adult pheasants are not large consumers of insects and other invertebrates in comparison with plant food eaten. The common belief that grasshoppers are consumed in large quantities is not borne out by the investigation.

Iowa quail and pheasants in winter: Severe winter in 117 years takes heavy toll, W. E. GREEN and W. E. BREED (*Amer. Wildlife*, 25 (1936), No. 6, pp. 83, 84, 90-92, figs. 4).—A study of the effect of subzero weather and drifting snow on quail and pheasants during the winter of 1936 (the most severe in 117 yr.), conducted by the Iowa Experiment Station in the field, is reported. The pheasants were observed on a 3,840-acre area located in Winnebago County, northern Iowa, and the quail studies were made on 6,000 acres in Decatur and Wayne Counties in southern Iowa.

There was a loss of 250 of the 400 pheasants entering the winter on the observation area, of which 131 birds either froze or choked to death, or died from a combination of freezing and choking; 37 birds were found snowed under; 13 birds showed signs of pneumonia; 12 birds were illegally shot; only 1 pheasant showed evidence of starvation; and in only 1 case was it definitely certain that a bird had been taken by a predator. Of 218 quail lost during the winter of 1935-36, 160 died from cold and hunger, 51 were taken by raptors (largely Cooper's hawk), and 7 by foxes.

The high mortality that occurred was found to have been caused by the abnormally severe weather, food and cover on the area in the fall of 1935 having been sufficient to carry most of the birds through the winter under normal weather conditions. With pheasants, starvation and predation losses were negligible, the highest loss having been caused by freezing, choking, or a combination of the two. With quail, the agencies responsible for a high mortality were predators and the much more disastrous combination of hunger and cold. Even though predator loss was evident, it is probable that this high loss was related to the severe weather which weakened the birds and deprived the prey of much of their food supply and the predators of food other than quail.

A new fluke, *Prosthogonimus folliculus* n. sp. (Trematoda), from the American bittern, W. M. REID and A. E. FREEMAN, JR. (*Amer. Micros. Soc. Trans.*, 55 (1936), No. 3, pp. 366-368, fig. 1).—Contributing from the Kansas Experiment Station, the authors describe a fluke removed from the cloaca of an American bittern (*Botaurus lentiginosus* (Montagu)) at Manhattan, Kans., under the name *P. folliculus* n. sp.

Occurrence of haematozoa in some California birds and mammals, F. D. and S. F. WOOD (*Jour. Parasitol.*, 23 (1937), No. 2, pp. 197-201, figs. 12).—The results of the examination for hematozoa of the blood of 203 birds, comprising 21 species, and of 185 mammals, including 18 species and subspecies, are reported.

Studies on the endoparasitic fauna of Trinidad mammals.—V, Further parasites from the ocelot, T. W. M. CAMERON (*Canad. Jour. Res.*, 15 (1937), No. 1, Sect. D, pp. 24-27, figs. 2).—In continuation of this series of studies (E. S. R.,

77, p. 213) several nematodes are recorded from the ocelot (*Felis pardalis*), and the whipworm *Trichocephalis serratus* is described in detail.

The effect of the winter of 1935-36 on Wisconsin quail, A. LEOPOLD (*Amer. Midland Nat.*, 18 (1937), No. 3, pp. 408-416, fig. 1).—Data obtained in Wisconsin in the winter of 1935-36, which is thought to have wrought more destruction to bobwhite quail than any since the turn of the century (the mortality on measured samples having ranged from 30 to 83 percent), are given in tables and graphs. "The lethal effect is ascribed to 40 days of continuous cold and snow. The previous winter of 1934-35, as measured by a 'hardness test', was only 15 percent as severe; 1917-18, 72 percent. Fat, well-fed quail died in numbers, a phenomenon hitherto unrecorded. Some of these had ice under the wings. Many were imprisoned in snow. Attempts to develop a size index from body measurements, and an emaciation index from weight: length ratios, were unsuccessful."

A list is given of 12 references to the literature.

Protecting cherries from birds, H. A. CARDINELL (*Michigan Sta. Circ.* 160 (1937), pp. 22, figs. 7).—Presenting information on the tremendous losses caused by the depredation of birds, especially robins and starlings, the author describes and discusses a device that frightens birds by means of regularly timed explosions. This device, known as the automatic acetylene exploder and referred to on page 653 by McWhorter, was operated at moderate cost and at a great saving when considered in the light of the crop harvested. Robins, on the whole, were less frightened than the starlings, but there was no evidence in the 14- to 17-day period when protection seems necessary that any of the birds became accustomed to the explosions.

The parasites of pigeons in Canada, M. J. MILLER (*Canad. Jour. Res.*, 15 (1937), No. 4, Sect. D, pp. 91-103, figs. 17).—A review of all the helminths found in the domestic pigeon and notes on their distribution, location in host, and pathogenicity are presented, together with a list of 35 references to the literature. A check list of the parasites of pigeons, systematically arranged, with their distribution throughout the world, is included. Four species of trematodes, namely, *Brachylaemus fuscatus*, *Echinostoma erraticum*, *E. exile*, and *E. parvum*, have been experimentally introduced into the domestic pigeon, as have three species of nematodes, namely, *Oxyuris* *parvum*, *Tetrameres* (*Microtetrameres*) *helix*, and *Trichinella spiralis*. Three helminths, *Ascaridia columbae*, *Capillaria columbae*, and *E. parvum*, have been found in Canadian pigeons and are described, *E. parvum* being recorded for the first time in North America. The lip characteristics of *A. columbae*, until now little studied, are described in detail.

An ecological study of parasites of some North Carolina salamanders, J. S. RANKIN (*Ecol. Monog.*, 7 (1937), No. 2, pp. 169-269, figs. 15).—Following an introduction with references to the literature, an account of methods employed, and a summary of hosts examined, the ecology of the hosts examined, including their habitats and parasites of the hosts examined, and the ecology of parasites found, including parasitism and habitat, seasonal variation, host specificity, multiple infestation, size and age of host, and rare or accidental parasites, are considered. Parasite and host lists and keys to the parasites of North American salamanders are presented in two appendixes, and a bibliography of eight pages is included.

Studies on the heterophyid trematode *Anophallus venustus* (Ransom 1920) in Canada.—II, Life history and bionomics, T. W. M. CAMERON (*Canad. Jour. Res.*, 15 (1937), No. 2, Sect. D, pp. 38-51, pls. 3, figs. 8).—In continuation of his studies (*E. S. R.*, 76, p. 500), the author has found that the

eggs of this trematode pass into water, embryonate, and are swallowed by the snail *Goniobasis livescens*. They do not hatch in water. In the snail, multiplication through redia and daughter redia stages takes place and cercariae, with long flanged tails and pigmented eyespots, are produced. These escape into the water but have a free life of less than 48 hr. To survive during this period, they must penetrate the skin of a fish, a great variety of which are successful intermediaries. In the muscle of the fish the cercaria encysts to become metacercaria, which is however not immediately infective. Infection of the definitive host is by ingestion of the uncooked fish.

A catalog and host-index of the genus *Leucocytozoon*, G. R. COATNEY (*Jour. Parasitol.*, 23 (1937), No. 2, pp. 202-212).—A further contribution to the author's catalogs and host indexes of blood-inhabiting protozoa (E. S. R., 76, p. 244), in which 68 forms of the genus *Leucocytozoon* are listed in connection with a three-page list of references to the literature.

***Taenia saginata*: Its growth and propagation**, W. J. and H. B. PENFOLD and M. PHILLIPS (*Jour. Helminthol.*, 15 (1937), No. 1, pp. 41-48).—This report of studies conducted in Melbourne, Australia, relates to the length and color, rate of growth, number of segments in a complete worm, length of life, and the number of eggs in a ripe segment of *T. saginata*.

Our insect friends and foes and spiders (Washington, D. C.: Natl. Geogr. Soc., 1935, pp. [5]+252, [pls.] 66, [figs.] 159).—The contributions by W. J. Shewalter, J. I. Hambleton, W. M. Mann, J. E. Harris, H. E. Ewing, and L. Passmore here presented are accompanied by 64 pages reproducing over 500 insects and spiders and their habits in their natural colors by H. Murayama.

Some aspects of the role of water in insect hibernation, A. C. HOBSON (*Ecol. Monog.*, 7 (1937), No. 2, pp. 271-315, figs. 8).—Several aspects of the problem were studied during an investigation of the role of water in insect hibernation and are reported upon in this contribution from Minnesota. A three-page list of references to the literature is included.

Caustic potash preparations of insects and insect parts, W. A. RILEY (*Amer. Micros. Soc. Trans.*, 55 (1936), No. 4, pp. 510-512).—A description is given of a method of preparing whole mounts or parts of insects for study by the use of caustic potash, which has been found by the author to be the most satisfactory.

Some developments in economic entomology (*Indus. and Engin. Chem., News Ed.*, 15 (1937), No. 1, p. 4).—A brief review is given of the advances during the year in knowledge as relates to the surgical maggot secretions, pyrethrum—derris and cube, ovicides, fumigants, the relation of optical activity of organic compounds on toxicity, and wetting and spreading agents.

[Report of work in entomology by the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 181-187, 203, 204).—The work of the year reported upon (E. S. R., 75, p. 373) relates to termites (E. S. R., 75, p. 376); European corn borer control; corn earworm; carpenter ants in telephone poles; use of insecticides in apple orchards; white apple leafhopper; substitutes for lead arsenate in orchard sprays; oriental fruit moth; gypsy moth suppression; European pine shoot moth control; mosquito control; Japanese beetle control; oriental beetle; and, at the Tobacco Substation, control of flea beetles on tobacco.

[Report of work with economic insects by the Nebraska Station] (*Nebraska Sta. Rpt.* [1936], pp. 23-26).—Work conducted during the year (E. S. R., 75, p. 224) with the chinch bug, hessian fly, alfalfa weevil, corn earworm, grasshoppers, potato flea beetle, potato psyllid, codling moth, and attraction of insects to light traps is referred to.

[Report of work in economic entomology and zoology by the Ohio Station] (*Ohio Sta. Bul.* 579 (1937), pp. 43-53).—A report is made of the work of the year (E. S. R., 75, p. 374) with the annual white grub (*Ochrosidia villosa* Burm.) attacking lawns in Ohio, the gladiolus thrips, and the lacebug *Corythucha cydoniae* Fitch on *Cotonaster*, all by C. R. Neiswander; European corn borer resistance, weedy corn and the southern corn rootworm, and seed corn protection from birds, all by L. L. Huber; oriental fruit moth (E. S. R., 75, p. 814) and strawberry leaf roller, both by R. B. Neiswander; apple flea weevil, by J. S. Houser and R. B. Neiswander (E. S. R., 75, p. 673); forest insect survey, by Houser and [J. B.] Polivka; codling moth, including experimental spray program, and the round-headed apple tree borer, both by C. R. Outright; cotton aphid and cabbageworms (imported cabbageworm (E. S. R., 76, p. 830), cabbage looper, and diamondback moth), both by H. L. Gui; and the onion maggot influenced by weather, effect of different copper-lime ratios on the potato leafhopper (see p. 602), and variations in potato varieties to potato flea beetle attack, all by J. P. Slesman.

Insect pest conditions forecast, J. R. WATSON (*Fla. Grower*, 45 (1937), No. 5, p. 25).—A contribution from the Florida Experiment Station.

[Contributions on orchard insects and their control] (*Ill. State Hort. Soc. Trans.*, 70 (1936), pp. 251-259, 265-279, 431-456).—The contributions on orchard insects here presented (E. S. R., 75, p. 508), mostly from the Illinois Experiment Station, are Oriental Fruit Moth Studies in 1936, by S. C. Chandler and W. P. Flint (pp. 251-259); Recent Developments in Codling Moth Control in the Pacific Northwest, by E. J. Newcomer (pp. 265-272); Results of Orchard Insect Control Experiments for 1936, by W. P. Flint and S. C. Chandler (pp. 274-279); Personal Experiences With Codling Moth Control Methods, by F. Heaton, O. G. Jones, F. Hawkins, and R. Byers (pp. 431-437); Three Years' Tests With Fixed Nicotines, by W. P. Flint (pp. 438-444); The Codling Moth Survey of 1936, by S. C. Chandler and W. P. Flint (pp. 445-454); and The San Jose Scale Survey of 1936, by S. C. Chandler (pp. 454-456).

Experiments in the control of orchard insects, 1936, C. R. OUTRIGHT (*Ohio State Hort. Soc. Proc.*, 70 (1937), pp. 48-57).—This contribution from the Ohio Experiment Station refers to work in 1936 with the round-headed apple tree borer; field tests of new aphicides for the apple aphid; spray tests with new insecticides for the codling moth, apple maggot, apple aphid, European red mite, and plum curculio; sticker and spreader tests at Gypsum; and banding for the codling moth.

[Fruit pest control in the Northwest] (*Better Fruit*, 31 (1937), Nos. 7, pp. 3-5, 7, 8, figs. 2; 8, pp. 3-5).—Contributions presented in No. 7 include New Lead Arsenate Spray Combinations and How They Work, by J. Marshall and K. Groves (pp. 3, 4), contributed from the Washington Experiment Station; Phenothiazine, a Promising New Insecticide, by E. J. Newcomer (p. 5); Orchard Sanitation and Codling Moth Control, by A. D. Borden (p. 7); and Spraying Results [for the Codling Moth and San Jose Scale] in Idaho Prove Satisfactory, by W. H. Wicks (p. 8). Contributions in No. 8 include What Guide Should Be Employed in Choosing Spray Material, by L. Childs (pp. 3, 4), and The Spray Program for 1937, by R. L. Webster (p. 5).

Recommendations for codling moth and orchard mite control in Washington for 1937 (*Better Fruit*, 31 (1937), No. 9, pp. 3-5).—Recommendations for 1937 (E. S. R., 75, p. 375), prepared by the experiment station and extension service of the State College of Washington, the State department of agriculture, and the U. S. D. A. Bureau of Entomology and Plant Quarantine, are presented.

[Contributions on tree pests] (*Mass. Forest and Park Assoc., Tree Pest Leaflets 1* (1936), pp. [4], figs. 2; 2, pp. [4], figs. 2; 3, pp. [4], figs. 2; 4, pp. [4], fig. 1; 5, pp. [4], fig. 1; 6, pp. [4], figs. 3; 7, pp. 4, figs. 2; 8, pp. [4], fig. 1; 9, pp. [4], figs. 6).—These practical contributions relate, respectively, to (1) The Eastern Spruce Gall Aphid *Adelges abietis* (L.), (2) The Birch Leaf Skeletonizer (*Bucculatrix canadensisella* Chambers), and (3) The European Pine Shoot Moth (*Rhyacionia buoliana* Schiff.), all by R. B. Friend, contributed from the Connecticut [New Haven] Experiment Station; (4) The Beech Scale (*Cryptococcus fagi* (Baer.) Dougl., by R. C. Brown; (5) Tent Caterpillars (*Malacosoma disstria* Hbn. and *Malacosoma americana* Fab.), by J. V. Schaffner, Jr.; (6) The European Spruce Sawfly *Diprion polytomum* Hartig and (7) The White-Pine Weevil (*Pissodes strobi* Peck), both by H. J. MacAloney; (8) The Sugar Maple Borer (*Glycobius speciosus* Say, also *Synanthedon acerni* (Sesia)), by H. I. Baldwin, H. J. MacAloney, and H. B. Peirson; and (9) The Elm Leaf Beetle (*Galerucella xanthomelaena* (Schrank)), by P. A. Readio.

Fabric insects: How to combat them in the home, W. P. FLINT and W. E. McCauley (*Illinois Sta. Circ. 473* (1937), pp. 12, figs. 3).—A practical account of the carpet beetles, clothes moths, and the cigarette beetle, methods of preventing injury, and ways of destroying such fabric insects.

Insect transmission of virus diseases of plants, M. T. COOK (*Sci. Mo., 44* (1937), No. 2, pp. 174-177).—A brief practical discussion of the role of insects in the transmission of virus diseases of plants contributed from the Puerto Rico College Experiment Station.

Insects pollinating onions, F. R. SHAW and A. I. BOURNE (*Amer. Bee Jour., 76* (1936), No. 8, pp. 401, 402).—The data here contributed from the Massachusetts Experiment Station have been noted from another source (E. S. R., 74, p. 228).

A review of some recent experimental work with derris and pyrethrum, J. P. BARRETT (*Canad. Ent., 69* (1937), No. 4, pp. 73-77).—A brief review is given of some of the newer developments in the use of derris and pyrethrum.

The adsorption-absorption and translocation of derris constituents in bean plants, R. A. FULTON and H. C. MASON (*Science, 85* (1937), No. 2202, p. 264).—The data thus far obtained indicate that derris constituents of insecticides when applied as suspensions in water to bean plants are adsorbed-absorbed and translocated to new growth of such plants.

Magnesium sulfate: A new insecticide, H. W. and M. S. FRINGS (*Science, 85* (1937), No. 2209, p. 428).—Brief reference is made to tests of grasshoppers, which indicate that magnesium sulfate may be of insecticidal value in the control of mandibulate insects.

Nicotine peat: A new insoluble nicotine insecticide, L. N. MARKWOOD (*Indus. and Engin. Chem., 28* (1936), No. 5, pp. 561-563, figs. 4).—A water-insoluble insecticide was prepared by the reaction of nicotine and peat in aqueous solution. "A study of the factors involved showed that the nicotine content of the product is not greatly affected by the concentration of nicotine, the degree of dilution, or the ratio of peat to nicotine. The coarser particles of peat are combined with more nicotine than the finer ones. The presence of acid in the reaction reduces the nicotine content of the product. Peats vary in their capacity for holding nicotine. The highly acid peats combine with a greater amount of nicotine than the less acid or neutral peats. When peat is first treated with acids to remove inorganic basic constituents (calcium, magnesium, iron, aluminum, etc.), the nicotine content is increased and the proportion of soluble nicotine is reduced. The peats that are benefited most by the acid treatment are those of least natural acidity."

A new water-soluble nicotine insecticide—nicotine humate, L. N. MARKWOOD (*Indus. and Engin. Chem.*, 28 (1936), No. 6, pp. 648, 649, fig. 1).—In continuation of the above work, the author has found that "the liquid separated from nicotine peat also contains nicotine, not as the free base, but in combination with humic acid derived from the peat. This aqueous solution can be treated with alkali and the nicotine recovered by distillation, but since the compound in solution, nicotine humate, may have a usefulness of its own, it has been recovered unchanged by evaporating the water. Nicotine peat and nicotine humate are thus companion products formed in a single reaction. Nicotine humate is a black product, soluble in water, forming what is undoubtedly a colloidal solution." This is a stable product giving a clear solution in water, with from 28 to 34 percent of nicotine, depending on the type of peat from which it is made. "This yield is a function of the type of peat and its preliminary treatment and the ratio of peat to nicotine. The product has insecticidal possibilities similar to those of commercial nicotine sulfate."

Oil sprays: Chemical properties of petroleum oil unsaturates causing injury to foliage, R. P. TUCKER (*Indus. and Engin. Chem.*, 28 (1936), No. 4, pp. 458-461).—Experimental evidence is said to indicate that the unsaturated hydrocarbons of the lubricating fractions of petroleum oils are not toxic to foliage until they are oxidized to asphaltogenic acids. "At ordinary temperatures this oxidation takes place to a measurable degree only in the presence of air and light. Using apricot leaves as a testing medium, it was found that the toxic threshold is reached when approximately 0.5 percent of asphaltogenic acids are formed. The relation of viscosity and percentage of unsaturates present in a spray oil to its susceptibility to oxidation in light of various intensities is discussed."

The effect of soap sprays on plants, J. M. GINSBURG and C. KENT (*Jour. N. Y. Ent. Soc.*, 45 (1937), No. 1, pp. 109-113).—In work by the New Jersey Experiment Stations greenhouse, garden, ornamental, and orchard plants were sprayed with various concentrations of coconut oil soap in order to determine the maximum concentration that can be applied without injury. Concentrations of 0.25 percent of soap caused no injury to blossoms or foliage of any one of the plants tested; 0.5 percent produced no injury to foliage, stems, or buds but caused injury to delicate flowers; 1 percent, no injury to orchard trees but injured many greenhouse and garden plants; and 2 percent, injury to most of the plants tested.

W. S. C. "Dynamite" spray: How to mix and use it, J. MARSHALL and K. GROVES (*Better Fruit*, 31 (1937), No. 10, pp. 3, 4).—A practical contribution from the Washington Experiment Station, a reference to which by Webster has been noted (*E. S. R.*, 76, p. 830).

The relative toxicity of insect fumigants, H. H. SHEPARD, D. L. LINDGREN, and E. L. THOMAS (*Minnesota Sta. Tech. Bul.* 120 (1937), pp. 23, figs. 4).—The relative toxicity of most of the insect fumigants in commercial use is reported for the confused flour beetle, the granary weevil, and the rice weevil. Following a description of the method of determination of fumigant toxicity, the relative toxicity of fumigants to various insects, the toxicity of new compounds as insect fumigants, the relative susceptibility of different species to fumigants, the relation of toxicity to temperature, and fumigant penetration are dealt with, the details being given in tables and graphs.

"Some new compounds of high toxicity were investigated, as well as a number of chlorinated compounds closely related to those in common use. The latter arrange themselves in an orderly manner with respect to their relative toxicity and their chemical constitution. Methyl thiocyanate has noteworthy

toxicity greater than that for chloropicrin and approaching that for hydrocyanic acid. An apparent correlation of developmental temperatures and susceptibility to fumigants is pointed out in the case of some closely related insect species. The lower the temperature the less effective is a fumigant, to a certain point. Below about 10° C. (50° F.) the fumigant, however, becomes more effective the lower the temperature. This effect seems to be caused by the interaction of sublethal low temperature and low concentrations of the fumigant.

"The role of adsorption in the fumigation of stored goods, as well as their penetration by the fumigant, has been discussed. The relative importance of adsorption in fumigant problems is indicated by the results of preliminary experiments."

A list of 39 references to the literature is included.

Tables for rapid calculation of spray and dust requirements, R. L. McMUNN (*Ill. Hort.*, 26 (1937), No. 2, pp. [4-7]).—Tables are given showing the rate of application, correction factors, and amounts of spray per tree; calculation of spray materials required when the dilution is made in pounds or gallons per 100 gal. of water; correction factors for lime-sulfur of different strengths and the gallons and pints of lime-sulfur of different strengths to use in making up 100 gal. of spray and for calculating nicotine sulfate (40 percent only) requirements; equivalent amounts in pints, ounces, grams, and cubic centimeters of nicotine sulfate for different dilutions; calculation of pounds needed in making dust mixtures; and correction factors for varying rates of dust applications.

The nasute termites of the Philippines, S. F. LIGHT and F. J. WILSON (*Philippine Jour. Sci.*, 60 (1936), No. 4, pp. 461-520, figs. 26).—Sixteen new species are here described, making a total of 49 species of termites known to occur in the Philippines.

An ecological study of some Orthoptera of the Chicago area, H. F. STROHECKER (*Ecology*, 18 (1937), No. 2, pp. 231-250, fig. 1).—This contribution includes a review of the literature, presented with a list of 33 references.

Controlling grasshoppers in orange groves, J. R. WATSON (*Citrus Indus.*, 17 (1936), No. 11, p. 16).—A practical contribution from the Florida Experiment Station.

Studies on the embryology of the African migratory locust *Locusta migratoria migratorioides* Reiche and Frm., I, II, M. L. ROONWAL (*Roy. Soc. London Phil. Trans., Ser. B*, 226 (1936), No. 538, pp. 391-421, pls. 3, figs. 16; 227 (1937), No. 543, pp. 175-244, pls. 7, figs. 15).—Part 1 of this contribution deals with the early development, with a new theory of multiphased gastrulation among insects; part 2 with organogeny.

On some Thysanoptera from American conifers, J. D. HOON (*Ent. News*, 48 (1937), No. 3, pp. 74-80, fig. 1).—*Taeniothrips pini* (Uzel), a European species which feeds upon pine, spruce, and fir, is recorded from several islands in Lake Superior near Grand Portage, Minn., feeding on young needles of black spruce (*Picea mariana*), and on the same host in Canada across the Pigeon River from Minnesota. *Oxythrips coloradensis*, in flowers of *Pinus scopulorum* at Boulder, Colo., and *O. pinicola*, in the flowers of *P. canadensis* near Fraser, Colo., and on *Ribes cereum* growing among pines in Crater Lake National Park, Oreg., are described as new.

Notes on the distribution and hosts of some western Thysanoptera, S. F. BAILEY (*Ent. News*, 48 (1937), No. 2, pp. 43-49).—Notes are presented on 44 forms which supplement the account previously noted (*E. S. R.*, 75, p. 377).

Thysanoptera of Formosa, R. TAKAHASHI (*Philippine Jour. Sci.*, 60 (1936), No. 4, pp. 427-459, figs. 4).—An attempt has been made to list all of the species

of Thysanoptera known to occur in (Taiwan) Formosa, with brief biological notes on some of the forms. Two species and a variety are described as new.

Say's grain bug (*Chlorochroa sayi* Stal.) in Canada, L. A. JACOBSON (*Canad. Ent.*, 68 (1936), No. 11, pp. 259, 260).—Say's stinkbug, an outbreak of which in New Mexico in 1915-16 was studied by Caffrey and Barber (*E. S. R.*, 41, p. 355), made its initial appearance in Alberta in appreciable numbers in 1935 and is now present in all districts of southern Alberta where grains are grown. At the present time the only recommended control measure consists in the early spring burning of weeds and rubbish under which the adults pass the winter.

The potato leafhopper, J. P. SLEESMAN (*Ohio Veg. Growers Assoc. Proc.*, 22 (1937), pp. 69-75).—This contribution from the Ohio Experiment Station reports briefly upon the biology of the potato leafhopper, its injury to potato, relative number on potato varieties, and control. It is based upon experimental work in 1934, 1935, and 1936, the results of which are given in tables.

In the control work with bordeaux mixture, copper-lime dust, and dusting sulfur, a fine dusting sulfur was found equally as effective as 4-6-50 bordeaux mixture in restricting the leafhopper population, but the vines did not remain green as long and the injury was slightly less when sulfur was used. Dusting with freshly mixed 20-80 copper-lime dust was as satisfactory as spraying with a 4-6-50 bordeaux mixture only when the dusting was done at a time when the plants were wet with dew. Significantly higher yields were obtained when the lime content of the bordeaux mixture was reduced to one-half that of the copper sulfate, that is, a copper sulfate-lime ratio of 2 to 1. Population counts indicated that the number of nymphs does not vary significantly for the different bordeaux treatments, and that the differences in yield cannot be attributed to differences in leafhopper populations. There is strong evidence that copper in some manner exerts a stimulative action upon plant growth in addition to protecting the foliage against attack by insects and diseases.

Notes on the oviposition and life-history of the leafhopper *Oncometopia undata* Fabr. (Homoptera: Cicadellidae), R. B. SWAIN (*Ent. News*, 47 (1936), No. 10, pp. 264-266).—A résumé of life history studies of *O. undata* conducted at the U. S. D. A. Bureau of Entomology field laboratory at Webster Groves, Mo., in 1933 is presented.

Philippine Cicadellidae (Homoptera), G. MERINO (*Philippine Jour. Sci.*, 61 (1936), No. 3, pp. 307-400, pls. 4).—In this contribution the author has described or determined 83 species of Cicadellidae, 85 of which are new and 14 recorded from the Philippine Islands for the first time. Three genera (*Rorarella*, *Omanella*, and *Alituralis*) are erected. A check list of the Philippine forms with the original bibliography and synonymy is included.

A study of potato psyllid yellows in Wyoming, G. HARTMAN (*Wyoming Sta. Bul.* 220 (1937), pp. 40, figs. 6).—Tests and observations made during the last two seasons for the control of the potato or tomato psyllid *Paratrioxa cockerelli* Sulc. and potato psyllid yellows are reported upon, the details being given in seven tables. It is concluded that the winter home of this insect is local, the insects increasing to numbers sufficient to produce damaging infestations in potato fields by the latter part of June or the first part of July, and the severity of the infestation depending upon the temperature conditions. Potatoes in the field appear to be damaged but little, if any, by potato psyllids until they have reached the budding or early blooming stage of growth. Potato fields planted June 1 appear to be damaged to a less extent than fields planted before that time.

"Lime-sulfur is an effective control for the damage to yields of potatoes caused by the potato psyllid. Pressure of from 300 to 400 lb. per square inch should be used in applying the spray. Three sprays should be applied per season in early planted fields, while two applications seem to be sufficient in late planted fields. Spraying potato vines before the first flower buds appear does not seem to benefit the potato plants and may result in injury. Spraying potato fields when psyllid nymphs are not present upon the vines gave no beneficial results in 1936 when yields were used as a measure. Where psyllid nymphs were present upon the potato vines, spraying with lime-sulfur spray increased the yield and improved the quality of the tubers harvested.

"There is not, at present, any known method of forecasting the extent of psyllid infestation before the first of July each year. There is no indication that the symptoms produced upon potatoes by the action of psyllids is carried from one season into the next by tubers from affected plants. The symptoms are produced only after psyllid nymphs have been present upon the vine. A few standard varieties appear to be partially resistant to the effects of the psyllid. These varieties may be used by the small grower for home consumption but are not to be recommended at the present time for the commercial potato grower in Wyoming."

The control of aphids on apples in Virginia, W. S. HOUGH (*N. J. State Hort. Soc. News*, 18 (1937), No. 2, pp. 891, 892).—A practical contribution from the Virginia Experiment Station.

Control of the rosy and green apple aphids in Ohio, C. R. CUTRIGHT (*Ohio State Hort. Soc. Proc.*, 70 (1937), pp. 166, 168, 170, 171).—A practical contribution on the rosy apple aphid and the apple aphid from the Ohio Experiment Station.

Warble fly control in Canada, A. GIBSON and C. R. TWINN (*Sci. Agr.*, 17 (1936), No. 4, pp. 179-198; *Fr. abs.*, p. 198).—Studies of warble flies (the common cattle grub and the northern cattle grub) and their control, conducted in western Canada at Indian Head, Sask., and at Kamloops and near Salmon Arm, B. C., and in eastern Canada in the Provinces of Ontario and Quebec, are reported upon, the details being given in tables.

The larval stages of *Wohlfahrtia vigil* (Walker), E. M. WALKER (*Jour. Parasitol.*, 23 (1937), No. 2, pp. 163-174, figs. 24).—A description is given of the three larval stages of this sarcophagid flesh fly.

On the biology of the black scale *Chrysomphalus aonidium* L. in the Jordan Valley, H. Z. KLEIN (*Hadar*, 10 (1937), No. 1, pp. 3, 4, 6-8, figs. 4).—A study of the Florida red scale made in the Jordan Valley in 1933-34 is reported. Four, and occasionally five, generations were found to occur, the fertility of the species being 2.8 times as great as that of the California red scale. The species was found chiefly in the northern part of Palestine, but it spreads very rapidly and penetrates into every grove in the first years of fruit yielding.

Natural mortality of black scale during the winter of 1935-1936, R. H. SMITH (*Calif. Citrogr.*, 22 (1936), No. 2, p. 59).—A limited study of the mortality of black scale during the winter of 1935-36 is compared with the findings of previous winters (*E. S. R.*, 74, p. 821).

Biological notes on the Chrysopidae, W. L. PUTMAN (*Canad. Jour. Res.*, 15 (1937), No. 2, Sect. D, pp. 29-37, fig. 1).—Further biological and ecological data on the Chrysopidae (*E. S. R.*, 68, p. 69; 69, p. 548), gathered during a study of the predators of the oriental fruit moth, are presented. The species concerned are *Chrysopa rufilabris* Burm., *C. plorabunda* Fitch, *C. doxonesi* R. C. Smith, *C. oculata* Say, *C. nigricornis* Burm., *Meleoma signoretti* Fitch, and *M. emuncta* (Fitch). Data on life history include relation of development to temperature,

number of generations, method of overwintering, and oviposition. The early stages of *C. doirnesi*, *M. signoretti*, and *M. emuncta* are described. Seasonal prevalence and fluctuations in abundance from year to year are discussed, and notes are given on natural control agencies. The value of chrysopids in the biological control of the fruit moth is summarized, with the conclusion that only in exceptional seasons are they of appreciable importance.

The biology of some Minnesota Trichoptera, D. G. DENNING (*Amer. Ent. Soc. Trans.*, 63 (1937), No. 1, pp. 17-44, figs. 48).—A contribution from the Minnesota Experiment Station.

Biology of the tobacco moth and its control in closed storage, W. D. REED and E. M. LIVINGSTONE (*U. S. Dept. Agr. Circ.* 422 (1937), pp. 39, figs. 22).—This report on studies and observations at Richmond, Va., of the life history and distribution of the tobacco moth during the years 1931-34, earlier accounts of which by Buck and Reed (*E. S. R.*, 64, p. 547) and by Reed, Livingstone, and Morrill, Jr., (*E. S. R.*, 69, p. 690) have been noted, summarizes the present knowledge of the pest in the United States, where it was first discovered in infested tobacco and reported upon in 1930, including its injury to tobacco, several stages, seasonal history, life history as studied in 1932 and 1933, and control.

A list is given of 22 references to the literature.

The European pine shoot moth in Sweden, T. PARR (*Jour. Forestry*, 35 (1937), No. 3, pp. 269-273, fig. 1).—A brief outline of the biology, relations to host trees, parasites and predators, and control of the European pine shoot moth, of which there is a heavy infestation in some extensive plantations of Scotch pine in southern Sweden, presented with a list of 15 references to the literature.

The introduction and colonization in Puerto Rico of beneficial insects parasitic on the pink bollworm of cotton, K. A. BARTLETT (*Puerto Rico Sta. Agr. Notes* No. 77 (1937), pp. 5).—In reporting upon work with parasitic enemies of the pink bollworm in Puerto Rico, a discussion of the importance of the pink bollworm as a factor in the production of long-staple cotton is followed by accounts of the introduction of more than 58,000 parasites of this bollworm, the life histories of the three imported species, namely, *Chelonus Blackburni*, *Eriocrania roborator*, and *Microbracon kirkpatricki*, of liberations of these species in cotton-growing areas, the finding of a single native parasite (*Perisicrola* sp.) of the pink bollworm, and the recovery of all liberated species.

Adjusting the spray program and materials to control the codling moth, W. S. HOUER (*Md. State Hort. Soc. Proc.*, 39 (1937), pp. 58-60).—A brief practical contribution from the Virginia Experiment Station, presented before the Maryland State Horticultural Society at Hagerstown, Md., in January 1937.

Codling moth (*Maryland Sta. Rpt.*, 1936, pp. XXXVII, XXXVIII).—Brief reference is made to the work of the year with two types of lead arsenate and with fish oil soap as a spreader in codling moth control.

Beta naphthol bands for codling moth control, A. M. WOODSIDE (*Va. Fruit*, 25 (1937), No. 2, pp. 12, 14, 16).—The results obtained in 1936 (*E. S. R.*, 75, p. 376) with two brands of commercial bands and several types of home-made bands are reported upon.

The commercial bands proved superior in killing power, due it is thought to their having had a more even coating of chemical than is usually possible to obtain in home-made bands. "The addition of aluminum stearate to the dipping mixture did not increase the efficiency of the bands. Bands made with old oil drained from automobile crank cases gave as good results as bands made with new oil. Mixing the oil and beta-naphthol in a colloid mill

apparently did not increase the efficiency of the bands. Bands made from Cod-Ban, a proprietary mixture of oil and beta-naphthol, were generally more effective than other home-made bands with the same weight of coating. This is probably due to the oil and beta-naphthol being more intimately mixed than is possible with home-made mixtures, and to the beta-naphthol being in a finer condition."

A table is given showing the cost of banding per tree and per 100 worms destroyed during the 4 yr. 1933-36.

Chemically treated codling moth bands, F. SHEERMAN III (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 222-227, figs. 4).—This practical contribution deals with the preparation of trees for banding and the application of bands, including proprietary treated bands, proprietary cold-dip mixtures, and home prepared hot-dip bands, and the dipping of the bands.

The hatching of spores of *Nosema bombycis* Nägeli and the partial development of the organism in tissue cultures, W. TRAGER (*Jour. Parasitol.*, 23 (1937), No. 2, pp. 226, 227).—The author reports upon the emergence from the spore and the development of *N. bombycis* in silkworm tissue cultures.

European corn borer investigations: Experiments with insecticides on early sweet corn, C. H. BATCHELDER, D. D. QUESTEL, and N. TURNER (*Connecticut [New Haven] Sta. Bul.* 395 (1937), pp. 269-285, figs. 5).—A report is made of investigations undertaken by the station and the U. S. Department of Agriculture, cooperatively, for the purpose of determining the effectiveness of preparations of fixed nicotine, rotenone, and phenothiazine when employed against the first generation of the European corn borer under conditions prevailing in Connecticut. Several of the preparations that showed outstanding insecticidal effectiveness during the experiment are compared diagrammatically. All of the materials tested in field plats were highly toxic to larvae, the fact that some proved more suitable for general use than others being attributed to their superior physical properties, such as suspensibility, adhesiveness, and proportion of active particles in the residue.

"The attempt to develop a suitable dry concentrate of fixed nicotine which could be prepared in advance of its use as a spray, and stored, was not productive of an insecticide that withstood weathering satisfactorily. This is probably attributable to the loss of desirable physical properties that occurs when these materials are dried and reground. Likewise, a concentrate of nicotine and tannin in alcohol did not provide corn-plant protection equivalent to that of the field-reacted nicotine tannate standard.

"Tests of ground derris spray containing 4 lb. of derris to 100 gal. of water showed consistently satisfactory control when compared with the nicotine tannate standard used in the same spray schedule. Phenothiazine, when applied as a spray at the rate of 4 lb. per 100 gal. of water, was found to compare favorably with the nicotine tannate standard in reducing the number of borers infesting corn. Two grades of this material were tested in the field experiments, a recrystallized and a technical grade of relatively high purity. Both preparations provided satisfactory protection against corn borer infestation. Experiments undertaken for the purpose of determining the effectiveness of insecticides applied in dust form showed that the preparations of derris, phenothiazine, and nicotine tannate used were satisfactory. However, a newly developed preparation, dual-fixed nicotine, consisting of nicotine tannate and nicotine bentonite, gave a degree of control consistent with commercial requirements."

Tomato fruit worm: Field control, J. J. DAVIS (*Canner*, 84 (1937), No. 12, II, pp. 125, 126; also in *Canning Trade*, 59 (1937), No. 36, pp. 12, 14, 16).—Reporting from the Indiana Experiment Station it is pointed out that since field control of the corn earworm as a pest of tomato by the use of insecticides is

expensive and uncertain every other control practice should be understood and applied. Practices from the beginning of harvest until the tomatoes go into the finished product should be carefully supervised by the grower. There is considered to be a real need for a much more carefully planned and executed study of the physiology of the insect, with special reference to attractive baits for the moths as well as the possible attractiveness of restricted light waves; also a very complete study of cropping practices as related to abundance on tomatoes.

The introduction and colonization in Puerto Rico of beneficial insects parasitic on the sugarcane moth borer, K. A. BARTLETT (Puerto Rico Sta. Agr. Notes No. 78 (1937), pp. 8).—After pointing out that the sugarcane borer through killing young plants and weakening older plants is the most important pest of sugarcane in the Western Hemisphere, accounts are given of introduced parasites, outlines of their life history, rearing of the Amazon fly *Metagonistylum minense* in the laboratory, liberation of beneficial species with the details in table form, and the aid of native parasites in borer control.

Resistance of winter wheats to hessian fly, W. R. FOSTER and C. E. JEFFERY (Canad. Jour. Res., 15 (1937), No. 4, Sect. C, pp. 135-140).—In investigations at Saanichton, B. C., it was found that the stage of growth at the time of spring emergence of the hessian fly apparently accounted for the differential resistance of varieties of winter wheat. The varieties more advanced in growth appeared to be more resistant or freer from infestation than varieties less advanced. "There was a positive correlation ($r = +0.84$) between the number of days to maturity and infestation, and a negative correlation ($r = -0.63$) between the height of the wheat and infestation on April 1, about the time the fly emerges. . . .

"Nitrate of soda, superphosphate, and a complete fertilizer broadcast or drilled had no significant effect on hessian fly damage."

Studies on the higher Diptera of medical and veterinary importance.—The bot flies of the subfamily Oestrinae, W. S. PATTON (Ann. Trop. Med. and Parasitol., 31 (1937), No. 1, pp. 113-125, figs. 10).—A continuation of the studies previously noted (E. S. R., 77, p. 222).

Infestation of oranges by the Mediterranean fruit fly during the autumn in Palestine, E. RIVNAY (Hadar, 9 (1936), No. 5, pp. 134, 135, 137).—The various seasonal infestations of oranges by the Mediterranean fruitfly are considered. The infestation of citrus during the late summer and autumn is said to be due primarily to a premature ripening of the fruit, which may be caused by (1) late spraying with oil emulsion against the [California] red scale, (2) trees planted in too light, poor, and dry soil, (3) insufficient irrigation, or the exploitation of the moisture in the ground by cypress and eucalyptus trees, and (4) falling trees.

Studies on the genus Rhagoletis (Trypetidae), with special reference to Rhagoletis pomonella (Walsh), A. D. PICKETT (Canad. Jour. Res., 15 (1937), No. 3, Sect. D, pp. 53-75, figs. 25).—An investigation of the biological and morphological relations of a number of species of the genus *Rhagoletis* is reported upon. An extensive study of the forms which develop in apple, hawthorn, and blueberry from the standpoint of their relations to their hosts led to the conclusion that they represent the single species *R. pomonella* (officially known as the apple or blueberry maggot), the females showing a decided preference to oviposit in the host in which they developed as larvae. A list of 35 references is included.

Descriptions of genera and species of the dipterous family Ephydriidae, [I], II, E. T. CRESSON, JR. (Amer. Ent. Soc. Trans., 61 (1935), No. 4, pp. 345-372; 62 (1936), No. 4, pp. 257-270).—Three new genera (*Dagus*, *Paracoenia*, and

Parascatella) and 23 new species are included in the first contribution and 8 new species in the second.

Additional data on the biology and ecology of *Strigoderma arboricola* Fab. (Scarabaeidae, Coleoptera), C. H. HOFFMAN (*Bul. Brooklyn Ent. Soc.*, 31 (1936), No. 3, pp. 108-110; *abs. in Minnesota Sta. Rpt. 1936*, p. 27).—Reporting upon the biology of *S. arboricola*, earlier work upon which by Hayes has been noted (E. S. R., 46, p. 252), it was found that fertile females deposit their eggs singly in the soil after a preoviposition period of 11 days. The duration of the egg stage varied from 11 to 25 days. The three grubs reared to maturity required from 160 to 164 days to complete their larval development on bluegrass sod. Since the feeding habits of the larva have not been determined under field conditions, the economic status of this stage is unknown. The prepupal period requires approximately 6 days and the pupal period about 13 days. Adults are attracted to many flowers in various habitats, and when abundant cause considerable damage to cultivated roses by feeding on the buds and flowers.

Seasonal trends in the relative abundance of Japanese beetle populations in the soil during the annual life cycle, H. Fox (*Jour. N. Y. Ent. Soc.*, 45 (1937), No. 1, pp. 115-126, figs. 2).—Records kept of field surveys of the abundance of the soil-inhabiting population of the Japanese beetle conducted throughout the greater part of each year in a group of eight stations, all situated within 12 miles of the original point of entry of the beetle and covering a total range of seven consecutive years, reveal certain clearly defined trends in the course of its annual life cycle.

"The general trends shown in Japanese beetle populations as regards relative abundance during the annual life cycle are consecutively as follows: (1) A rapid increase beginning late in June and extending through the summer, coincident with the season of active egg deposition, resulting in (2) the population reaching its maximum abundance early in September. This is followed by (3) a brief interval of rapid decrease lasting until mid-October, (4) a long period of little or no apparent change extending through the winter and until about May 1 of the succeeding year, and (5) a second period of rapid decrease extending through May and into June, when adult emergence begins."

Pasture renovation in relation to populations of white grubs, R. F. FUELLEMAN and L. F. GRABER (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 3, pp. 186-196, figs. 2).—In renovation work in portions of 30 old bluegrass pastures in 1934 and 1935 by the Wisconsin Experiment Station, consisting of the establishment of dry-weather legumes, including alfalfa, sweetclover, and red clover, in permanent pastures without plowing, as described by Graber,⁵ the populations of white grubs of the genus *Phyllophaga* in October 1935 and in the summer of 1936 were very small and injury was practically eliminated. In only 4 of the 15 renovations of 1934 were any white grubs found, and these with only 4,000 to 8,000 grubs per acre. In the adjacent unrenovated grass the grubs were present at the rate of 34,848 to 314,000 per acre, except in two densely sodded pastures, where no grubs were found in either the renovated or unrenovated portions. Compared with untreated grass, the 15 renovations of 1934 reduced the grub populations by an average of 98 percent.

In the 15 areas renovated in 1935 only 1 was free of white grubs, the remainder containing populations ranging from 3,178 to 74,000 per acre. In the unrenovated pastures from 47,916 to 333,000 grubs per acre were found. The average reduction in grub populations due to the renovations of 1935 was 91 percent. Renovation was much more effective in lowering the populations of

⁵ Wis. Agr. Col. Ext. Circ. 277 (1936), pp. 23, figs. 16.

white grubs when it preceded the beetle flights of 1934 and 1935 than when it preceded that of 1935 only. Dense growths of dry-weather legumes reduced grub populations effectively, whether these plants were in the seedling or later stages of growth.

Control of potato flea beetles, F. A. HERMAN and J. F. HOCKEY (*Sci. Agr.*, 17 (1936), No. 4, p. 264).—Control work with the potato flea beetle on a small area of tomato plants on August 20, 1936, to determine the effect of Cubor dust "75" (0.75 percent rotenone) and derris-gypsum dust (0.4 percent rotenone) is briefly referred to. Within an hour of a 6 p. m. application of the dust the ground was thickly dotted with wriggling beetles, and all were dead the following morning. No live beetles were found on the plants when examined 2 days later, and the control of the pest appeared to be practically complete. Ten days after the application the tomato plants were found to have occasional leaflets with from 3 to 5 beetles present and feeding.

An adjacent unsprayed plat of potatoes was found to have from 0 to 19 flea beetles per leaflet actually feeding. An application of 12-8-80 copper arsenate-lime dust was made on August 25, and the beetles were still present and feeding when examined a few days after treatment.

Recent developments affecting bark beetle control in Minnesota, L. W. ORN (*Minnesota Sta. Rpt.* 1936, p. 29).—Continuing earlier work (E. S. R., 74, p. 524), the author reports having found that control work for the bark beetles *Ips pini* and *I. grandicollis* cannot be conducted effectively during the period from November to May, since a large proportion of the overwintering adults are hibernating in the litter under the trees. "When beetle infestations occur following light ground fires, severe defoliation by other insects, prolonged drought or other injury, the affected trees should be removed and treated. The method of treatment will depend upon the state of development of the beetle brood. Young broods composed of eggs, larvae, and pupae can be killed by simply removing the bark from the infested material. Older broods, including young adults, can be killed by placing the infested logs in water or by spraying the logs with oil and then burning them sufficiently to scorch the bark. Infested material that is not valuable enough to save for wood or lumber should be piled or burned. The boles removed from the stand in connection with thinning and other cultural operations should be piled so as to hasten seasoning or should be removed from the area."

Notes on the wharf borer *Nacerda melanura* L., R. E. BALCH (*Canad. Ent.*, 69 (1937), No. 1, pp. 1-5).—Borers which riddled timbers in a wharf at Saint John, N. B., and required reconstruction owing to decay were found to be larvae of the edemerid beetle *N. melanura*. The notes presented relate to its biology, economic importance, and means of prevention.

Notes on the biology of the partridge-pea weevil *Chalcodermus collaris* Horn. (Coleop., Curculionidae), J. ALSTERLUND (*Ent. News*, 48 (1937), No. 2, pp. 31-35, pl. 1).—Observations of *C. collaris*, which was reared from the seed pods of the partridge-pea (*Cassia chamaecrista*) at Urbana, Ill., are reported.

The pepper weevil, C. G. GOFF and J. W. WILSON (*Florida Sta. Bul.* 310 (1937), pp. 12, figs. 3).—This bulletin reports upon the appearance of the pepper weevil in Florida, its importance as a pest, observations of its life history, host plants, and control, and gives descriptions of its several stages.

An account of this weevil in the Southwest by Elmore, Davis, and Campbell in 1934 has been noted (E. S. R., 72, p. 511).

Changes in weight and nitrogen content of adult worker bees on a protein-free diet, M. H. HAYDAK (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 10, pp. 791-796).—A report is made of an experiment conducted by the Wisconsin

Experiment Station in which bees of a known age were fed a pure carbohydrate diet for a period of 189 days, the bees in the last sample having been 236 days old. Weekly changes in the fresh and dry weight and in the nitrogen content of heads, abdomens, thoraces, and whole bees were ascertained.

"There was a substantial decrease both in weight and in nitrogen content of all parts of the bodies of the experimental bees, the greatest change taking place in the abdomens. A final decrease in the percentage of dry matter and of nitrogen in the fresh and dry weights occurred in the experimental bees. A slight increase in the dry matter of the heads and intestines and a considerable increase in the percentage of nitrogen in the dry matter of abdomens were exceptions. The significance of the latter findings is discussed. The greatest variation was in the percentage of dry weight and of nitrogen in the abdomens of the experimental bees. The smallest variation was in the thoraces. The necessity of removing the intestines before analyzing insects is emphasized."

The honeybee as pollinator of cultivated blueberries, F. R. SHAW and J. BAILEY (*Amer. Bee Jour.*, 77 (1937), No. 1, p. 30).—The observations reported have led to the conclusion that (1) the varieties of blueberries tested were practically self-sterile, (2) the honeybee can and does pollinate the flowers of the varieties of blueberries used, and (3) bumblebees, solitary bees, and honeybees are all important pollinators of cultivated blueberries. Their relative importance as pollinators remains to be determined.

Burnet as a pollen plant, J. E. ECKERT (*Amer. Bee Jour.*, 77 (1937), No. 3, pp. 118, 119, figs. 2).—It is claimed that the rosaceous forage plant *Sanguisorba minor*, known as burnet, an introduced species little known in this country but cultivated to a considerable extent in England and France, deserves the consideration of beekeepers in drought areas where there is a shortage of pollen and even in the irrigated areas where pollen plants are scarce after the close of fruit bloom. This plant withstands heavy pasturing in favorable locations, continuing to grow during the winter period, and is for this reason commonly used in pasture mixtures in England. Once well established it will withstand protracted periods of drought and should be well adapted to dry foothill situations in the coastal ranges of California, at the experiment station of which State it has yielded from 600 to 700 lb. of seed per acre.

Lespedeza as a honey plant, F. VAN HALTERN (*Amer. Bee Jour.*, 76 (1936), No. 11, p. 546).—Notes are presented on a number of species of *Lespedeza* and their possible value as honey plants in the United States.

The nitrate reduction test and its significance in the detection of *Bacillus* larvae, A. G. LOCHHEAD (*Canad. Jour. Res.*, 15 (1937), No. 3, Sect. C, pp. 79-86).—In this further contribution (*E. S. R.*, 70, p. 367), the author reports having found that "*B. larvae* differs from most nitrate-reducing species in its ability to accumulate nitrite in nutrient solutions containing but small amounts of nitrate (0.001 percent). Most nitrate-reducing organisms show no accumulation of nitrite at this concentration owing to assimilation of nitrate or disappearance of nitrite through reduction or assimilation. With many nitrate-reducing bacteria disappearance of nitrite keeps pace with nitrite formation only up to a certain concentration, varying with the organism, above which nitrite may accumulate.

"The ability of *B. larvae* to accumulate nitrite in semisolid carrot or turnip extract media with no added nitrate is of considerable aid in the cultural test for this organism. Of five other organisms concerned with brood disease or occurring as contaminants in comb, which were grown in association with *B. larvae*, none showed interference with accumulation of nitrite by the latter except *B. orpheus*. With this species a positive nitrite test was dependent on

the relative development of the organisms, *B. larvae* exerting a certain antagonistic action. None of the eight species of bacteria tested prevented recognition of growth of *B. larvae* in the semisolid medium."

Descriptions and records of Nearctic mutillid wasps of the genera Myrmilloides and Pseudomethoca (Hymenoptera: Mutillidae), C. E. MICKEL (*Amer. Ent. Soc. Trans.*, 61 (1935), No. 4, pp. 333-398).—This contribution from the Minnesota Experiment Station presents records, notes, and descriptions of new species of two mutillid genera. A revised key to the genus *Pseudomethoca* Ashmead is included.

A revision of the genus Megachile in the Nearctic region, IV-VI, T. B. MITCHELL (*Amer. Ent. Soc. Trans.*, 62 (1936), Nos. 2, pp. 117-166, pls. 4; 4, pp. 323-382, pls. 5; 63 (1937), No. 1, pp. 45-83, pls. 2).—This contribution from the North Carolina Experiment Station is a continuation of the author's revision of the genus (E. S. R., 74, p. 524).

Control of injurious insects by a beneficial parasite, C. H. ALDEN and J. E. WEBB, JR., (*Ga. Dept. Ent. Bul.* 79 (1937), pp. 23, figs. 10).—The results of work conducted in Georgia since 1929, in which year a laboratory was erected at Cornelia, on the mass production of the egg parasite *Trichogramma minutum* and of the Angoumois grain moth, employed as a host in mass production, are reported. The details of colonization work in codling moth and oriental fruit moth control are given in 11 tables. Parasites were also used as an aid in the control of the pecan shuck worm, nut casebearer, leaf casebearer, budworm, hornworm, and grain moth. The parasites have been colonized in 93 counties, being used to reduce the insect infestation on apple, peach, pecan, and truck farms. During the period 1929-36, 138,210,250 parasites were furnished to Georgia farmers.

"Many experiments were conducted to determine the effectiveness of *T. minutum*. The peach experiments showed that in 1931 the infestation in the colonized areas was 16.3 percent fruit moth at harvest and 31.5 percent fruit moth in noncolonized areas at harvest. In 1936 the infestation in colonized areas was 0.15 percent, and in the noncolonized areas 0.55 percent. Fruit moth egg collections showed an average parasitism of 46.0 percent in 1930, 125 percent in 1931, and 36.1 percent in 1932. The apple experiments showed that in 1933 the infestation in colonized areas was 32.4 percent codling moth at harvest and 60.6 percent codling moth in the noncolonized areas at harvest. In 1935 the infestation in colonized areas was 16.2 percent and in the noncolonized areas was 24.3 percent. During the period of the tests 31,632 codling moth eggs were collected in various apple orchards in the State. The highest number of eggs found parasitized at any one collection was 97.6 percent in 1933 and the lowest 0.0 percent in 1933 and 1934; the highest yearly average for the period was 77.6 percent in 1932 and the lowest yearly average 26.2 percent in 1936."

A map and photographs are given which show the distribution of parasites by crop and counties and the type of equipment used in the production of the parasite.

The distribution of black widow spiders, B. J. KASTON (*Science*, 85 (1937), No. 2194, p. 74).—In this contribution from the Connecticut [New Haven] Experiment Station, attention is called to records of the occurrence of *Latrodectus mactans* (Fab.) in States overlooked in some earlier reports. Several new records of the occurrence of this spider in Connecticut and Vermont are given, together with a list of 15 references to the literature.

The black widow spider in Virginia, H. A. ALLARD (*Science*, 85 (1937), No. 2194, pp. 74, 75).—Observations of the habits of this spider (*Latrodectus mactans*), with records of its occurrence in Virginia and Georgia, are noted.

Notes on the distribution of the black widow spider, L. D. ANDERSON and H. G. WALKER (*Science*, 85 (1937), No. 2195, pp. 100, 101).—Data on the occurrence of *Latrodectus mactans* are given in this contribution from the Virginia Truck Experiment Station.

Contributions to the knowledge of the red spiders in Palestine, I, II, H. Z. KLEIN (*Hadar*, 9 (1936), Nos. 4, pp. 107–111, figs. 4; 5. pp. 126–132, figs. 8; 9, pp. 195, 197–199, figs. 3; 10, pp. 219, 220, 222, 223, 225, figs. 3).—This contribution is presented in two parts.

I. *The oriental red spider Anychus orientalis* Zacher (pp. 107–111, 126–132).—A report of studies of the biology and control of the most important of the red spiders attacking citrus in Palestine. There are 18 generations during the year in the coastal plain area, where its life cycle may be completed in the summer in a period of 8 days. Control work has shown that vegetoalkaloids do not destroy the pest, and that emulsions of white oil in a concentration of 1.5 percent for spraying and sulfur for dusting are the only materials of value.

II. *The common red spider Epitetranychus althaeae* V. Hanst (pp. 195, 197–199, 219, 220, 222, 223, 225).—The biology and control of the common red spider, which in Palestine frequently appears in the spring on citrus leaves in nurseries and young groves the first year after planting and inflicts damage identical with that caused by *A. orientalis*, are reported upon. It has been found to rear over 20 generations during the year in the coastal plain of Palestine. Up to the time of writing, 63 host plants had been discovered in Palestine, 60 percent of which are cultivated plants, about 10 percent being trees and 90 percent grasses, bushes, and creepers. The pest is controlled by dusting with sulfur or spraying with a white oil emulsion of 1.5 percent if applications are made immediately upon its first appearance.

Ornithodoros turicata: The possible vector of relapsing fever in southwestern Kansas.—Preliminary report, G. E. DAVIS (*Pub. Health Rpts. [U. S.]*, 51 (1936), No. 50, p. 1719).—Approximately 2,000 specimens of *O. turicata*, hitherto not known to occur in Kansas, were collected in Clark County, where 11 cases of relapsing fever occurred from 1931, to 1934, inclusive. Other cases have since been reported from this and nearby counties.

"The various stages of this tick were found in rodent burrows, in holes in sand, and attached to cottontail rabbits, one immature jack rabbit, spermophiles, prairie dogs, prairie-dog owls, and terrapins. Eleven hundred and ninety-seven ticks were removed from a single sand hole which contained 11 terrapins (*Terrapene ornata*). These ticks were later tested for spirochetes at the Rocky Mountain Laboratory by permitting them to engorge on white rats. Three strains of spirochetes were recovered from three localities, viz, from ticks collected from a prairie dog burrow in the south-central part of Clark County, from a sand hole (no host present) in the extreme eastern part, and from a cottontail rabbit burrow in the face of a limestone outcropping in the extreme western part. The prairie dog burrow was located on a ranch where a case of relapsing fever had occurred."

Six years' intensive observation on the seasonal prevalence of a tick population in western Montana.—A preliminary summary, C. B. PHILIP (*Pub. Health Rpts. [U. S.]*, 53 (1937), No. 1, pp. 16–22, fig. 1).—The results of a study of the adult Rocky Mountain spotted fever tick (*Dermacentor andersoni*) population on the vegetation of a 40-acre tract in the Bitterroot Valley of Montana are reported. The findings are based upon draggings made biweekly or weekly, according to conditions, through the tick season of 1930 and the five following seasons.

ANIMAL PRODUCTION

The American Society of Animal Production: Record of proceedings of the twenty-ninth annual meeting, November 27 and 28, 1936 (*Amer. Soc. Anim. Prod. Proc.*, 1936, pp. 341, figs. 13).—This is a report of the annual meeting held at Chicago in 1936 (E. S. R., 75, p. 527). The following papers were presented in the dairy cattle, beef cattle, swine, horse, sheep, nutrition, and meats sections:

A Symposium on the Increased Use of Forage and Roughage in Livestock Production, by W. J. Loeffel (pp. 9-12); Increased Use of Roughage and Pasture in Production of Beef Cattle, by F. G. King (pp. 12-15); Increased Use of Forage and Roughage in Dairy Production, by C. F. Huffman (pp. 15-21); Increased Use of Pasture and Forage in Sheep Production, by A. E. Darlow (pp. 21-24); The Increased Use of Forage and Roughage in Horse Production, by C. W. McCampbell (pp. 24-26); Possibilities of Increasing the Use of Forage and Roughage in Swine Production, by W. E. Carroll (pp. 26-29); Procedure in Pasture Research, by E. B. Forbes (pp. 32-37); Fundamentals of Successful Breeding, by A. J. Glover (pp. 37-41); Effect of Rock Phosphate on the Dairy Cow, by W. P. Elm-die (pp. 44-48); The Occurrence of Milk Fever in the Kentucky Station Herd Over a Period of Twenty Years, by H. J. Metzger and H. B. Morrison (pp. 48-52); The Relation of Age at First Calving to Butterfat Production in the First Five Lactations, by A. B. Chapman and G. E. Dickerson (pp. 52-55); Performance of Dairy Cows on an Unusual Calcium-Phosphorus Ratio, by A. H. Kuhlman, E. Weaver, W. D. Gallup, and A. Nalbandov (pp. 55-57); Make Worn Out Land Pay in Pasture for Beef Cattle, by E. S. Good (pp. 58-60); The Use of Varying Quantities of a 45 Per Cent Protein Supplement in a Ration for Fattening Calves, by P. Gerlaugh (pp. 60-63); Barley as a Feed for Beef Cattle, by A. D. Weber (pp. 63-67); Finish in Beef Cattle From the Standpoint of the Consumer, by R. M. Watkins (pp. 67-70); Fattening Steers on Pasture, by E. F. Rinehart (pp. 70-72); A Method of Measuring Performance in Beef Cattle, by W. H. Black and B. Knapp, Jr. (pp. 72-77); A Preliminary Study of Variations in Free-choice Intake of the Components of a Standard Ration and Breeding as Possible Factors in the Occurrence of Lameness in Pigs, by N. R. Ellis, W. A. Craft, and J. H. Zeller (pp. 77-81); The Utilization of Oat Meal Feed by Growing, Fattening Swine in Dry-Lot, by A. W. Lathrop and G. Bohstedt (pp. 82-87); Making Cottonseed Meal Safe and Effective When Fed as the Only Protein Concentrate to Pigs in Dry Lot, by W. L. Robison (pp. 87-91); Preliminary Report on Values of Pastures for Fattening Pigs in Louisiana, by C. I. Bray (pp. 91-93); A Study of Methods for Obtaining Measurements of Swine, by R. W. Phillips and W. M. Dawson (pp. 93-99); Boar Semen Studies.—A Preliminary Report, by F. F. McKenzie, J. C. Miller, and L. C. Bauguess (pp. 99-102); Swine Production in the Southeast, by W. G. Kirk (pp. 103-106); Distillery Slop as a Feed for Pigs, by E. J. Wilford (pp. 106-110); Hardness of Dent Corn as a Factor in Its Nutritive Value for Fattening Pigs, by A. L. Anderson, C. C. Culbertson, J. L. Robinson, and W. E. Hammond (pp. 110-114); Reed Canary Grass Hay for Fillies, by A. L. Harvey (pp. 114, 115); Barren Mares, by J. P. Hutton (pp. 116-118); Subject Matter in Freshman Courses Pertaining to Horses, by A. B. Caine (pp. 119-123); My Impressions of English Horse Breeding, by H. D. Linn (pp. 123-126); Horse Extension Activities That Bring Results, by L. P. McCann (pp. 126-130); The Kellogg Institute of Animal Husbandry, by G. H. Hart (pp. 130-135); Training Horses for Work and Pleasure, by J. A. Gorman (pp. 135-137); Cottonseed Meal as a Feed for Ponies, by M. G. Snell (pp. 138-140); Bureau of Animal

Industry Program for Horse Improvement, by J. O. Williams and H. C. McPhee (pp. 141-143); Digestion Experiments With Mixtures of Sweetclover and Albit Wheat Forage Ensiled and Cured as Hay, by J. Sotola (pp. 143-147); The Digestibility of Range Bunch Grasses Fed Alone and Supplemented to Sheep, by R. McCall (pp. 147, 148); Predicting the Yield of Raw Wool From Its Density Under Pressure, by R. H. Burns and A. Johnston (pp. 148-155) (E. S. R., 77, p. 526); A Comparison of Fleeces from B and C Type Rambouillet Ewes, by J. M. Jones, P. Homeyer, S. P. Davis, W. H. Dameron, and B. L. Warwick (pp. 153-158); The Effect of Feed on Quality of Lambs, by C. Harper (pp. 158-162); A Comparison of Temporary Forage Crops for Lambs and Sheep, by J. P. Willman (pp. 162-165); Fattening Late Native Lambs, by L. A. Weaver (pp. 165-169); The Persistence of Stomach Worms on Bluegrass Pasture, by W. G. Kammlade, R. Graham, and L. E. Boley (pp. 169-172); The Middle Ground in Finishing Livestock to Meet Market Preferences, by C. D. Lowe (pp. 197-201); Sweetening Dry Bluegrass, by L. F. Graber (pp. 201-204); The Soil Conservation Program and Its Effect on Meat Animal Production, by I. B. Johnson (pp. 204-208); Lamb Feeding in the Indianapolis Area, by S. Meiks (pp. 208-212); The Objectives and Functions of the National and Local Live Stock Exchanges, by P. G. Adams (pp. 212-217); Grass and Turnips and the Part They Play in Meat Production in Britain, by W. Biggar (pp. 217-221); The Mortality of Calves in the Iowa State College Dairy Herd, by J. Ingels and C. Y. Cannon (pp. 223-229); The Rate of Breeding and Lambing and the Length of Gestation Period of Range Ewes, by D. W. Chittenden and A. H. Walker (pp. 232-236) (E. S. R., 77, p. 526); The Nutritive Instincts and Food Habits of Superior Individuals as Guides to the Nutritional Requirements of the Group, by W. F. Dove (pp. 243-247); The Value and Limits of Usefulness of the Insensible Loss in Weight as a Measure of Heat Production of Cattle, by M. Kriss (pp. 265-272); Does the Calcium or Phosphorus Content of Common Mineral Mixtures Conform to Experimental Findings? by G. Bohstedt (pp. 272-278); Digestible Nutrients and Metabolizable Energy in Russian Thistles, and in Light and Heavy Wheat and Barley and in Emmer, by F. W. Christensen and T. H. Hopper (pp. 279-282); Some Observations Pertaining to Tenderness of Meat, by D. L. Mackintosh, J. L. Hall, and G. E. Vail (pp. 285-289); The Influence of Retarded Growth in Lambs on Flavor and Other Characteristics of the Meat, by N. G. Barbella, O. G. Hankins, and L. M. Alexander (pp. 289-294); The Relation of Degree of Finish in Cattle to Production and Meat Flavors, by G. A. Branaman, O. G. Hankins, and L. M. Alexander (pp. 295-300); and Things Stockmen Do That Affect Their Returns, by R. C. Ashby (pp. 300-304).

[Investigations with Livestock in Nebraska] (*Nebraska Sta. Rpt.* [1936], pp. 9, 26-33, 34-36, 41, 44, 45).—Beef cattle studies reported include a comparison of cottonseed cake, tankage, and 37 percent protein soybean cubes as supplements to a silage ration and to a corn-alfalfa ration for fattening steers; corn silage v. corn and weed silage (approximately 50 percent weeds) for steer feeding; grainless silage, cottonseed cake, and a half feed of corn for wintering yearling and calf heifers and the time and feed requirement for finishing these heifers; and molasses v. corn for yearling heifers. At the North Platte Substation tests were conducted on feeding steers on native grass and alfalfa pasture, wintering steer calves, and the use of varying properties of barley in the steer fattening ration, and at the Valentine Substation on the effect of winter rations on the development of range heifers that calve as 2-year-olds

Swine tests yielded information on full feeding pigs on Sudan grass; various process soybean oil meals for feeding pigs in dry lot, and protein supplementary mixtures for pigs in dry lot. Tests at the North Platte Substation are noted on soybean oil meal, fish meal, and Wheatland milo for fattening hogs.

From sheep studies results are noted on the corn and alfalfa hay rations for fattening lambs, dry-lot summer rations for native lambs, cane molasses in the lamb fattening ration, and the effect of injection of serum from a pregnant mare on earliness of conception of ewes.

Experiments with poultry gave results on the nutrient requirement for growing chicks and poults; the effects of additions of iron to a standard ration for growing turkeys; the comparative efficiency of various proteins in poultry feeding; the effect of fineness of grinding on the palatability of poultry feeding stuffs; the use of pigweed seed in a ration for chicks; the comparative value of rye, cooked rye, and wheat in poultry rations; the value of different qualities of alfalfa in a chick ration; and from the Valentine Substation flock testing to determine the extent and influence of differences in turkey flocks.

[Investigations with Livestock in Ohio] (*Ohio Sta. Bul.* 579 (1937), pp. 84-93, 112-114, 122, figs. 2).—Beef cattle studies reported include varying proportions of corn and legume hay in rations for fattening steers, by P. Gerlaugh and C. W. Gay; the acre returns from corn fed as silage and as corn-and-cob meal plus bundle stover both for yearling steers and steer calves, by Gerlaugh and H. W. Rogers; the addition of protein supplement to a full feed of corn for calves on pasture, and the optimum quantity of protein supplements for fattening steer calves, both by Gerlaugh; and the mechanical and biological processing of feeds for cattle, by Gerlaugh, C. H. Kick, A. J. Schalk, and E. A. Silver.

Swine tests yielded information on a method for making cottonseed meal a safe and effective supplement for pigs, dried skim milk and solvent and expeller soybean oil meals for pigs in dry lot, and various tankage materials as protein supplements for pigs, all by W. L. Robison; and dry-rendered reduction and packing plant tankage for pigs, by Robison, P. A. Jones, and R. C. Beatty.

From sheep studies data are reported on the calcium requirements of lambs, by D. S. Bell, Kick, and B. H. Edgington; winter rations for ewes and lambs, and feeding western lambs, both by Bell; and winter roughages for sheep, by Bell and Foley.

Nutrition experiments reported include the efficiency of vitamin D from cod-liver oil and irradiated cholesterol for laying hens, and the stability of carotene and vitamin A in a mixed ration, both by R. M. Bethke, P. R. Record, and O. H. M. Wilder; vitamin G (flavin) studies with chicks, by Bethke and Record; the vitamin G (complex) requirements of the chicken, by C. H. Hunt, Record, and Bethke; the vitamin A requirements of laying birds, by Record, Bethke, Wilder, and V. D. Chamberlin; and methods of separating the various constituents that make up the vitamin B group, by Hunt. Poultry tests include methods of feeding layers, soybean hay v. alfalfa for layers, and management tests with chicks and growing pullets, all by D. C. Kennard and Chamberlin.

Feeds and feeding, abridged, F. B. MORRISON (*Ithaca, N. Y.: Morrison Pub. Co., 1937, 7. ed., pp. VI+503, figs. 126*).—The seventh edition of this popular text, adapted and condensed from *Feeds and Feeding* (twentieth edition) (E. S. R., 77, p. 11), is noted.

The composition of grass laid up for winter keep, B. THOMAS and B. M. BOYNS (*Empire Jour. Expt. Agr., 4* (1936), No. 16, pp. 363-378).—Information is presented from Armstrong College, Newcastle, England, on the composition of winter herbage on two permanent pasture areas which had been protected from grazing from August 4 to October 27, and one of which was grazed throughout

the winter period. Samples were taken on October 17 and at 4-week intervals thereafter until April.

The nutritive value of winter grass, as judged by its chemical composition, is inferior to summer grass but showed a relatively high mineral content and was similar in feeding value to month-old summer grass from an inferior pasture area. It is suggested that the practice of laying up grass for winter grazing may be considered a useful means of feed conservation.

Water soluble carbohydrates in forage crops and their relation to the production of silage, J. K. WILSON and H. J. WESS (*Jour. Dairy Sci.*, 20 (1937), No. 5, pp. 247-263).—This contribution from the [New York] Cornell Experiment Station presents information on the water-soluble carbohydrate content of a considerable number of leguminous and nonleguminous plants. Analyses were made on freshly cut samples collected at various stages of maturity. Results are expressed as the percentage of fermentable carbohydrates in the sap of the plant, in the fresh and dry weight of the plant, and in the moisture calculated to a uniform 80-percent basis for each sample. Nonleguminous plants averaged very much higher in water-soluble carbohydrates than the legumes, which probably explains why the latter crops so frequently failed to produce a silage of satisfactory quality. A number of silage-making trials are reported in which various grasses and legumes were ensiled with additions of fermentable sugars such as corn sugar and molasses. Also mineral acids and mixtures of organic and mineral acids were employed to reduce the pH of the material to a point which greatly reduced the microbial activity. It is shown that legume silages of superior quality can be produced by these methods. The desirability of phosphoric acid as a preservative is suggested.

The effect of feeding cobalt to rats, S. W. JOSLAND (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 5, pp. 474-480, figs. 4).—This study was undertaken following observations that the addition of small quantities of cobalt in the diet prevented ailments in sheep and other livestock (*E. S. R.*, 76, p. 250; 77, p. 390). The addition of 1 percent of anhydrous cobalt sulfate to the diet of two rats produced an intense polycythemia and loss of body weight within a 7-week period. There was a marked increase in the cobalt content of the carcasses as compared with control animals, the highest relative storage and the greatest concentration of cobalt occurring in the liver whereas in normally fed rats the highest concentration occurred in the pancreas. There was no evidence of cirrhosis in the liver of the rats receiving the cobalt supplement.

The distribution of magnesium in the animal organism and the effect of dietary magnesium, I. J. CUNNINGHAM (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 4, pp. 419-423).—Data are presented on the magnesium content of the bone ash of various portions of the sheep skeleton, the magnesium content of various organs of sheep, cattle, and rats, and the effect of various levels of magnesium intake on the magnesium content of certain organs, blood, and bone of rats.

The distribution of magnesium appears to be uniform throughout the bones of an individual animal. The content of this element in a given organ is closely similar in individuals of the same or of different species, but there is considerable variation in the content in various organs and muscles of a single individual. In rats severe dietary restriction of magnesium reduced its content in blood serum and bone only, while increased intake resulted in a marked increase in bones and blood serum, other organs of the body being unaffected.

The anti-hemorrhagic vitamin, H. J. ALMQUIST (*Poultry Sci.*, 16 (1937), No. 3, pp. 166-172).—This is a review of the available information on the anti-hemorrhagic vitamin, the material being classified under the following sub-

headings: (1) Preliminary indications of existence, (2) proof of existence as a new dietary factor, (3) functional properties, (4) physical and chemical properties, and (5) methods of determination. An extensive bibliography is appended.

Chemical and physical studies on the antihemorrhagic vitamin, H. J. ALMQUIST (*Jour. Biol. Chem.*, 117 (1937), No. 2, pp. 517-523).—Based on further studies of the yellow, viscous oil concentrate of the antihemorrhagic vitamin previously described (E. S. R., 76, p. 581), results are presented indicating that the antihemorrhagic vitamin is a complex, colorless, unsaturated substance, markedly unstable to alcoholic alkalis even in the absence of air. The concentrate contained a small amount of nitrogen, but no sulfur or phosphorus. Color tests indicated the presence of the indole nucleus. The concentrate is inactivated by exposure to direct sunlight, either under an atmosphere of carbon dioxide or under vacuum.

The gizzard factor of the chick, H. J. ALMQUIST and E. L. R. STOKSTAD (*Jour. Nutr.*, 13 (1937), No. 4, pp. 339-350, fig. 1).—This report essentially confirms previous findings by the authors (E. S. R., 76, p. 88). The results definitely indicate that gizzard erosions or lesions of the chick are caused by a deficiency in the diet of a fat-soluble factor which is not identical with any of the known vitamins. The comparative potencies of a considerable number of supplements with reference to their ability to prevent hemorrhagic and gizzard erosions are indicated, with evidence that the two factors can be clearly differentiated. Fresh and dried greens and wheat bran are considered the best practical sources of the gizzard factor. It appears to be quite unstable, being readily destroyed by heat and by alcoholic potash. It is readily adsorbed from hexane solution by activated magnesium oxide and appears to be in the saponifiable fraction. It is concluded that the presence or absence of gizzard erosions or of the gizzard factor in the ration does not appreciably affect the growth rate of chicks.

The multiple nature of the vitamin D of fish oils, C. E. BILLS, O. N. MASSENGALE, M. IMBODEN, and H. HALL (*Jour. Nutr.*, 13 (1937), No. 4, pp. 435-452).—The authors have assayed the liver oils of 25 species of fish for vitamin D potency in comparison with cod-liver oil on both rats and chickens. The relative effectiveness of the vitamin D for chickens, rat unit for rat unit, is expressed on the basis of cod-liver oil=100. On this basis, oils from the bluefin tuna of California were relatively the least effective for chickens, while the oil from the white sea bass of California was approximately 18 times as effective. Other oils covered a lesser but wide range of effectiveness, some of them closely resembling cod-liver oil. It is concluded that these observed differences in effectiveness were due to the existence of two or more forms of vitamin D. Irradiated ergosterol was less effective for chickens than any of the fish oils. Irradiated 7-dehydrocholesterol was about the same as cod-liver oil or irradiated ordinary cholesterol but inferior to that of white sea bass liver oil.

Composition of bones: Note on some New Zealand bones—normal and abnormal, M. W. YOUNG (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 4, pp. 391-395).—This report from the New Zealand Department of Agriculture presents data on the composition of the femur bones of sheep grown on normal or good livestock-producing areas, including animals from 4 mo. to 4 yr. of age, to indicate the effect of age on bone composition. Comparable data are presented for sheep grown on five areas in which pasture composition was abnormal and stock trouble had been experienced. In all cases the bones of sheep grown on the deficient areas were abnormal and were generally characterized by a high percentage of water and a low ash: organic matter ratio.

Studies in mineral metabolism.—XXXIV, The effect of sulphur upon the weight and wool production of sheep when food intake is not limited, P. J. DU TOIT, A. I. MALAN, J. W. GROENEWALD, and M. L. BOTHA (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 7 (1936), No. 1, pp. 181-188, fig. 1).—Continuing this series (E. S. R., 76, p. 373), the findings of this study indicate that 5 g. of sulfur per sheep daily can be fed over a prolonged period without detrimental effects. The body weight, food consumption, and wool production are apparently not significantly affected by the sulfur administered.

Gradients in wool growth, A. B. WILDMAN (*Nature [London]*, 139 (1937), No. 3511, pp. 285, 286).—Analysis of wool fibers from Suffolk, Cheviot, and Welsh Merino sheep indicated the existence of a definite britch-poll gradient in mean fiber fineness similar to the britch-poll fiber-type array gradient suggested by Galpin (E. S. R., 76, p. 519). There was also evidence of a main anteroposterior gradient in number of fibers per unit area and in straight length of fiber. These conditions may be explained on the basis of greater physiological skin activity in the forward parts of the body than in the britch region, this greater activity being expressed by a greater number of follicles and number of fibers per unit area and not by the production of coarser fibers.

Some characteristics which enter into the assessment of wool quality, and their estimation in the fleece, A. B. WILDMAN (*Jour. Textile Inst.*, 27 (1936), No. 7, pp. 181-193, fig. 1).—This report deals primarily with a preliminary study of methods of fleece sampling and analysis, chiefly for fineness, length, density, and kemp production. The methods employed are fully described. Statistical analysis of a limited amount of data indicates a significant variation in fiber fineness and possibly in fiber density between various areas on the body, but there was a tendency for mean length of fiber to be constant throughout the fleece.

Crimp of Merino wool a periodic function of time? J. C. SWART and J. J. J. KORZÉ (*Empire Jour. Expt. Agr.*, 5 (1937), No. 17, pp. 69-74, figs. 5).—Studies at the Stellenbosch-College of Agriculture, Union of South Africa, on the length and crimp of wool fibers from Merino wool showed considerable variation in the number of crimps and length of fibers composing a sample from a 4 sq. cm. area of body surface. The average correlation coefficient between number of crimps and length of fibers was found to be 0.921 ± 0.048 ; and the regression values ranged from 1.3 to 2.1 crimps for each 5 mm increase in length of fiber. The decrease in number of crimps per unit of straight fiber length as fiber length increases is attributed to an increase in the depth and spacing of crimp as the fiber length increases.

Seasonal variations in lamb-skins, with special reference to the sudoriferous glands, P. WHITE and F. G. CAGHLEY (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 5, pp. 466-473, figs. 16).—In this study a number of lambs were slaughtered at the first of each month, and samples were taken from the fresh skins. By making a detailed study of the sudoriferous glands according to described technic, it was evident that as perspiration is increased due to seasonal or other conditions these glands may enlarge to such an extent as to impair the leather-producing quality of the skins, resulting in the production of soft, spongy, or "loose" leather. As the necessity for perspiration decreased the size of these glands readily decreased.

Karakul fur sheep breeding, K. JAHN (*Chicago: Breeder Pubs.*, 1937, pp. 128, [figs. 34]).—This book is intended to familiarize the Karakul sheep breeder or prospective breeder with practical suggestions, reports, statements, and experimental work done in this branch of the fur industry.

The influence of soybeans upon the gains, feed requirements, and character of the fat produced when fed to growing and fattening spring pigs on rape pasture, C. C. CULBERTSON, B. H. THOMAS, F. J. BEARD, and W. E. HAMMOND (*Iowa Sta. Anim. Husb. Leaflet 150 (1936)*, pp. 6).—Eight types of rations were compared in this study. Cracked shelled corn was the basis of all, and all lots of pigs were on rape pasture and were self-fed a mineral mixture. Various protein supplements included tankage self-fed, cracked soybeans self-fed, and additions of 5, 10, and 20 percent of cracked soybeans, 10 percent of soybean oil meal, or 9.9 percent of soybean oil meal plus 1.3 percent of soybean oil with corn, the grain mixtures being self-fed in all cases.

Pigs receiving soybeans free choice consumed a heavy allowance, particularly during the latter part of the trial, amounting to about 12 percent of the ration over the entire period. Corn consumption was correspondingly reduced and the rate of gain per unit of feed was relatively high. The pigs receiving 10 percent of soybean oil meal made slightly more rapid gains and required less feed per unit of gain than those receiving 10 percent of cracked soybeans. Additions of soybean oil to the corn-soybean oil meal ration improved its effectiveness in promoting gains. Soybeans in the diet had a pronounced detrimental effect on the hardness of the fat. The iodine number of the fat from pigs receiving no protein supplement and the above-listed supplements in order averaged 68.87, 67.91, 78.76, 72.98, 79.99, 85.25, 71.92, and 79.17, respectively. It is concluded that more than 5 percent of soybeans in the ration over the entire growing and fattening period will result in undesirable carcasses from the standpoint of the firmness of the fat.

White rats as experimental animals in studies on the soft-fat problem, H. E. ROBINSON, R. E. GRAY, and R. C. NEWTON (*Food Res.*, 1 (1936), No. 5, pp. 413-418).—This is the report of two series of experiments designed to study the comparative effect on rats of rations known to produce varying degrees of hardness of fat in swine. The first series of diets was similar in composition to swine rations reported above and the second series was designed to test the value of adding highly saturated fats to diets containing large amounts of soybeans and peanuts.

While rats apparently deposited a somewhat softer fat than swine, the general effect of the rations was quite similar in both types of animals, there being a striking parallel in the character of the body fat formation. The addition of saturated fats of high melting point and low iodine number tended to offset the effect of soybean or peanut oils. It appears that rats are satisfactory experimental animals for use in studying the soft-fat problem.

Calcium and phosphorus supplements for growing swine, H. H. MITCHELL, W. E. CARROLL, T. S. HAMILTON, W. P. GARRIGUS, and G. E. HUNT (*Illinois Sta. Bul.* 434 (1937), pp. 13-54).—The results of four experiments are reported on (1) a comparison of complex v. simple mineral mixtures, (2) the comparative values of bonemeal, limestone, and rock phosphate as calcium supplements, (3) the comparative utilization of phosphates and normal carbonate of calcium, and (4) the likelihood of phosphorus deficiency in ordinary swine rations. The paired feeding technic was employed in all trials, and the effectiveness of the various mineral supplements was judged according to the rate of growth of the pigs, the weights and chemical analyses of the bones, and the retention of minerals and nitrogen as determined by metabolism studies.

The use of a very complex mineral mixture as a supplement to basal rations of either corn and tankage or corn and soybean oil meal proved no more effective than a simple supplement of common salt and steamed bonemeal in promoting growth and general health of the pigs. However, the addition of

ground limestone (15 g per head daily) to a basal ration of ground corn and soybean oil meal (with 1 percent of salt) produced heavier bones containing less moisture and more mineral matter and a higher percentage of both calcium and phosphorus in the bone ash.

Comparative trials with steamed bonemeal and ground limestone as supplements showed no significant differences in rate of gain of the pigs, although the bonemeal produced bones of greater weight and higher ash content. Rock phosphate fed at a level to supply 5 g of calcium daily exerted a definite and cumulative toxic effect which was greater than that produced by feeding pure tricalcium phosphate and calcium fluoride to provide the same intakes of calcium and fluorine. However, feeding rock phosphate at this level had no detrimental effect on the composition of the bones.

Ten-day metabolism trials with pigs variously receiving supplements of calcium carbonate and monocalcium, dicalcium, and tricalcium phosphates indicated no significant differences in the calcium retention from the carbonate, dicalcium phosphate, or tricalcium phosphate supplements, while retention on the monocalcium phosphate was slightly but significantly less.

Trials with various phosphate supplements indicated that in the presence of adequate calcium and vitamin D a phosphorus concentration of from 0.3 to 0.35 percent in a ration composed mainly of corn is adequate for maximum growth and bone development. A ration consisting mainly of corn and adequately balanced with respect to protein will not require a phosphorus mineral supplement. Under such conditions the only minerals required are salt and (if a vegetable protein concentrate is used) some form of calcium carbonate.

Studies in the quality of Maryland hams (*Maryland Sta. Rpt. 1936, p. XXIV*).—The effects of various curing mixtures and varying conditions in the storage chamber for curing hams are briefly noted.

The clinical examination of brood mares for pregnancy, W. W. DIMOCK (*Cornell Vet., 26 (1936), No. 4, pp. 314-323, figs. 2*).—The contribution from the Kentucky Experiment Station describes the main points to be observed in the successful clinical diagnosis for pregnancy in brood mares, with particular references to the palpation of the uterus through the rectum.

Scientific reports of the Sixth World's Poultry Congress [held at Berlin and Leipzig, July 24 to August 2, 1936] (*Wissenschaftliche Berichte des VI. Weltgeflügelkongresses, 1936. Leipzig: Reichsmin. Ernähr. u. Landw., 1936, vols. 1, pp. XX+367, figs. [54]; 2, pp. [VII]+276, figs. [46]; 3, pp. 550, figs. [19]; Eng. Summaries, pp. [XII]+94*).—The following papers in English, German, French, Italian, or Spanish, with abstracts in these languages (*E. S. R., 73, p. 222*), were presented in the various sections, those in the section on hygiene and disease being noted on page 702.

Résumés of these papers are in English in volume 3 (English edition).

Commercial poultry farming, T. B. CHARLES and H. O. STUART (*Danville, Ill.: Interstate Ptg. Co., 1936, pp. XVI+467, figs. 200*).—It is the object of this book to place at the disposal of poultrymen at large information relative to established and dependable practices in poultry production. Successive chapters deal with incubation, hatchery practices, brooding practices, battery brooding and laying batteries, broiler production, capons and caponizing, principles of feeding, feeding chickens, feeding adult birds, rearing and range management, selection, breeding and sex distinction, trapnesting and pedigreeing, improvement programs, marketing, fattening, housing and appliances, management factors, poultry diseases, and egg formation.

Some aspects of poultry breeding at the Livestock Research Station, Hosur, T. MURARI (*Agr. and Livestock in India, 7 (1937), No. 2, pp. 180-187*).—The comparative performances of various imported and native breeds of chickens in the Tropics and at latitude 55° N. are noted. Data are presented on the average egg size, adaptability, and resistance to disease for the various breeds. The results indicate that because of their superior adaptability and disease resistance more attention should be paid to the improvement of indigenous breeds.

Fecundity and reproductive ability in closely confined fowl, S. BIRD (*Sci. Agr., 17 (1937), No. 6, pp. 359-375, figs. 3; Fr. abs., p. 375*).—Data are presented on the production records of birds confined to individual cages to show that egg production was equivalent to or better than that of controls and the variability in production was only 75 percent as great. However, fertility and hatchability of fertile eggs were below the controls. Failure to consume sufficient calcium in the form of oyster shells and an excess of phosphorus in the ration are suggested as possible reasons for the low fertility and hatchability.

The relative value of farm grains in poultry nutrition, H. L. WILCKE (*Jour. Amer. Vet. Med. Assoc., 90 (1937), No. 2, pp. 188-193, figs. 2*).—The Iowa Experiment Station has determined the rate of growth of Single Comb White Leghorn chicks reared on rations in which ground yellow corn, ground wheat, or ground whole oats was the sole source of cereal grain, supplements of dried buttermilk, ground oystershell, steamed bonemeal, salt, and cod-liver oil being included in each ration. Oats proved to be the most satisfactory single grain, a ration containing 81.5 percent of oats with the above supplements producing good growth and excellent feathering. A ration containing the same amount of corn with the same supplements was not satisfactory from the standpoint of growth, feathering, or the number of cases of perosis which developed. Wheat in the ration gave results intermediate between those from oats and from corn. Apparently a factor essential for good growth and good feathering was present in oats and to a lesser extent in wheat, but was lacking in corn.

A note on the effect of different cereals in the fattening ration on the composition of the body fat of the fowl, E. M. CRUICKSHANK (*Jour. Agr. Sci. [England], 27 (1937), No. 2, pp. 309-315*).—Three rations in which 12 parts of dried skim milk were mixed with 88 parts of ground oats, corn meal, and

barley meal, respectively, were compared in 12-day fattening trials with both mature and immature Light Sussex cockerels. More rapid gains were secured on the immature lots, and with each age group ground oats promoted most rapid gains and corn the slowest gains. Analysis of body fat showed that the use of either corn or oats had no detrimental effect on the consistency of body fat. When fattening is rapid the type of fat deposited in the bird with corn is harder than that laid down on a normal ration of mixed cereals and protein supplement.

Effect of charcoal and length of storage on the calcifying property of cod liver, sardine (pilchard), and concentrated cod liver oils, L. L. LACHAT and H. A. HALVORSON (*Poultry Sci.*, 16 (1937), No. 3, pp. 147-154, fig. 1).—This describes a series of chick feeding trials in which the effectiveness of various rations tested were measured in terms of growth, percentage of mortality, bone ash content, and the reaction of bone sections to silver nitrate staining. In all cases where fed in combination, three times as much charcoal as oil was used.

In a trial with 9 groups of chicks on the A. O. A. C. rachitic ration in which a poor quality of cod-liver oil was fed at varying levels with and without charcoal, the charcoal exerted no appreciable effect either on the calcifying or growth-promoting properties of the oil. A series of trials was conducted with a basal ration composed of a mixture of 8 commercial feeds typical of commercial chick-growing mashers except that they contained no charcoal or cod-liver oil. Additions of poor quality, good quality, and concentrated cod-liver oils, and sardine (pilchard) oil, each separately and in combination with charcoal, were made to lots of the basal ration, and each was fed to groups of chicks over an 8-week growth period when the ration and supplements were freshly mixed and after 6 months' and 12 months' storage. This basal ration supplemented with charcoal but no vitamin produced subnormal growth and bone calcification. None of the above additions of oils or oil-charcoal mixtures showed any demonstrable effect on the growth-promoting or calcifying properties of the ration, either when newly mixed with it or after the storage periods.

Recent studies of vitamins required by chicks, T. H. JUKES (*Jour. Nutr.*, 13 (1937), No. 4, pp. 359-387).—This review covers primarily those investigations dealing with new essential dietary factors and recent reports of quantitative experiments with the older and better known vitamins in poultry nutrition. An extended bibliography is appended.

Further studies on vitamin G in chick nutrition with special reference to flavins, R. M. BETHEKE, P. R. RECORD, and O. H. M. WILDER (*Poultry Sci.*, 16 (1937), No. 3, pp. 175-182, figs. 2).—In these chick-feeding experiments, reported from the Ohio Experiment Station, a basal experimental ration of yellow corn 53, ground wheat 20, wheat bran 3, Argentine casein 12, steamed bonemeal 3, salt 1, and cod-liver oil 1 was used, mostly for an 8-week feeding period.

When the Argentine casein was replaced by domestic casein, domestic or Argentine casein washed with acidulated water, or purified (Labco) casein, the domestic product gave better growth and less leg disorder than the Argentine product, while the Labco product gave somewhat poorer results. Washing the domestic casein reduced its effectiveness, but had only slight effect on the Argentine product. Adding 3 percent of liver meal or replacing wheat with wheat germ in the basal diet greatly accelerated growth, and wheat middlings proved superior to wheat in the ration.

In a study of the effect of pH control in autoclaving on the growth-promoting and leg disorder factor the autoclaving of dried pork liver or yeast at an acid reaction for 6 hr. at 15-17 lb. pressure did not destroy this factor,

while at an alkaline reaction the factor was totally inactivated in the liver and partially destroyed in the yeast. When dried pork liver was subjected to different concentrations of cold ethyl alcohol, this factor was found to be soluble in 20 percent strength, partially soluble in 70 percent, but insoluble in 95 percent.

Adsorption experiments showed that the factor was adsorbed by fuller's earth from an extract of dried liver or dried whey, indicating that flavines were the principal factor involved. Feeding lactoflavine to chicks which had been on the basal diet for 2 weeks greatly stimulated growth and prevented the onset of the leg disorder. It is concluded that flavines are essential in chick nutrition, and that the beneficial effects from feeding meal, yeast, liver, etc., to poultry are largely due to the flavine content of these products.

Location of the antienzyme in egg white, J. S. HUGHES, H. M. SCOTT, and J. ANTELYES (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 4, pp. 310, 311).—The Kansas Experiment Station has studied the proteolytic activity of the three fractions of egg white, namely, the outer thin, the thick, and the inner thin portions, by incubating each fraction for 30 min. with a buffered solution of enterokinase. The results clearly indicate that most of the inhibitory substance responsible for the resistance of raw egg white of freshly laid eggs to proteolytic activity is located in the inner thin fraction.

Measurement of the viscosity of eggs by the use of a torsion pendulum, J. V. ATANASOFF and H. L. WILCKE (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 9, pp. 701-709, figs. 5).—This report from the Iowa Experiment Station describes a torsion pendulum apparatus used in determining the viscosity of eggs as measured by the effect of placing the egg in the pendulum system on the rate of decrease of the angular amplitude or damping of the system. Equations are presented for calculating the viscosity index value designated as K . A study of the relationship of the K value of 3,890 eggs to the yolk movement and yolk shadow of the eggs as observed by candling showed a correlation coefficient of 0.2388 for the former and 0.2236 for the latter. It is concluded that eggs having a low total viscosity index as measured by the torsion pendulum method are, in general, of poor quality, as judged by yolk movement and yolk shadow, although when individual eggs are studied there is more variation in the results than would be desirable from an experimental standpoint.

The pigment of egg shell membranes, A. A. KLOSE and H. J. ALMQUIST (*Poultry Sci.*, 16 (1937), No. 3, pp. 173, 174).—The California Experiment Station has made a spectroscopic analysis of the pigment extracted from eggshell membrane. It is concluded that this pigment is identical with a natural porphyrin, probably protoporphyrin, which has been identified as the pigment occurring in all pigmented eggshells. The spectra of the membrane pigment and the porphyrin correspond in neutral ether, dilute acid, or dilute alkaline solutions.

Variations in egg-quality characters in certain breeds, varieties, and strains of chickens, A. VAN WAGENEN, G. O. HALL, and H. S. WILGUS, JR. (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 10, pp. 767-777).—The [New York] Cornell Experiment Station has made observations on egg quality, including firm albumin score, height of firm albumin, percentage of firm albumin, shell strength, and the presence of abnormalities (meat or blood spots) on 3,043 eggs from 1,273 birds. These included 81 pens of Single Comb White Leghorns, 16 of Barred Plymouth Rocks, 10 of White Plymouth Rocks, 16 of Single Comb Rhode Island Reds, and 10 of New Hampshires entered in New York egg-laying contests. Gross correlations were calculated between the possible pairs of characters for each breed and for the group as a whole. Mathematically significant correlations were found in several instances between the observed condition of the firm albumin and the percentage of firm albumin. The White Leg-

horns showed greater variability between pens than within pens for these characters, indicating strain differences, but this was not evident in the American breeds observed. The percentage of firm albumin and shell strength did not differ importantly for the different breeds except for the Barred Rocks, which showed somewhat weaker shell strength. Meat spots were more prevalent in cases of the American breeds than those of the White Leghorns. None of the egg quality characters observed showed biologically significant interrelations with each other or with production except for the obvious relationship between the height and the condition score of the firm albumin, indicating that the characters used as measures of interior egg quality are independent of each other and are relatively constant for the individual.

Factors influencing production of clean eggs, E. M. FUNK (Missouri Sta. Bul. 584 (1937), pp. 12, figs. 4).—The information presented is based on observations extending over 15 mo. and including the classification of over 66,000 eggs with respect to cleanliness. Most of the soiling of eggs occurred in the nest, since more than 99 percent of all eggs were clean before they came in contact with the nest. Certain breed differences and also differences between individuals within a breed with respect to percentage of clean eggs produced occurred, evidently associated with the temperament and habits of the individuals. A higher percentage of clean eggs was produced during the hot and dry seasons of the year. The percentage of dirty eggs was reduced approximately 50 percent by gathering eggs four times per day as compared to gathering only at the end of the day, and there was a higher percentage of dirty eggs present in trap nests in the morning than in the afternoon. When open nests were used, darkening the nests materially decreased the percentage of dirty eggs. A higher percentage of clean eggs was gathered from trap nests than from open nests and from birds confined to laying houses than from those on range. Shavings, oat hulls, sawdust, and excelsior were the most effective nesting materials for preventing dirty eggs. Covering the droppings platform with poultry netting and using strips of gravel in front of laying houses did not significantly affect the percentage of clean eggs.

The comparative growth rates of turkeys, ducks, geese, and pheasants, T. T. MILBY and E. W. HENDERSON (Poultry Sci., 16 (1937), No. 3, pp. 155-163, figs. 10).—The comparative growth rates of White Pekin ducks, Toulouse geese, Bronze and White Holland turkeys, and ring-necked pheasants have been studied at the Iowa Experiment Station, and the data obtained, along with data from another source, on the growth rate of White Plymouth Rock chickens have been plotted to show the comparative growth curves of the various species. The growth rates of turkeys, chickens, and pheasants were of practically the same magnitude during the first few weeks after hatching, and these species followed the same rates of growth during other periods of constant growth rate, the only marked differences being that each growth period was more prolonged for the turkeys than for the chickens or pheasants. The ducks and geese were very much alike in their rates of growth, but their rate during the first few weeks was practically double that for chickens, etc., while the decline in growth rate was more pronounced and occurred at an earlier age. These results suggested that rapid early growth and quick attainment of the greater proportion of mature weight may be a characteristic of migratory species of fowls.

A contribution to the chemistry of turkey eggs, J. S. HEPBURN and P. R. MIRAGLIA (Jour. Franklin Inst., 225 (1937), No. 3, pp. 375-377).—Determinations are reported on the moisture, solids, ether extract, crude protein, ash and dextrose composition, and caloric value of the edible portion of six whole turkey eggs and the whites and yolks of five other eggs.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle in Nebraska] (*Nebraska Sta. Rpt.* [1936], pp. 10, 42).—Results are briefly noted on the vitamin A content of A. I. V., molasses, and ordinary corn silage, and of the milk from cows receiving these various silages as the only roughage; and from the North Platte Substation on pasturing the dairy herd on alfalfa.

[Investigations with dairy cattle and dairy products in Ohio] (*Ohio Sta. Bul.* 579 (1937), pp. 73-80, 81-83, fig. 1).—Brief reports are presented on the use of mineral acids in the preservation of legume silage, by C. C. Hayden, A. E. Perkins, W. E. Krauss, C. F. Monroe, R. G. Washburn, and C. E. Knoop; supplementing pastures for milking cows, and a study of the H-ion concentration of the bovine rumen, both by Perkins and Monroe; a sole roughage ration for raising dairy heifers, and studies on the iodine content of the bovine thyroid, both by Monroe; the effect of feeding menhaden oil on the percentage of butterfat in milk, by T. S. Sutton and Hildreth; the use of hormone preparations in the treatment of certain types of sterility in dairy cows, by Sutton; the effects of vitamin A deficiency on the central nervous system, by Sutton, Setterfield, and Krauss; iron and copper in a normal calf ration, by Knoop, Krauss, Sutton, and Washburn; and bone studies with dairy calves, by Knoop and Krauss.

Studies on the nutritive values of milk yielded information on the growth-promoting value of raw v. pasteurized milk, and of pasture milk v. dry-feed milk, both by Krauss; factors affecting the extent to which milk may be activated by irradiation, by Krauss, R. M. Bethke, and Washburn; technic for assaying vitamin D potency of milk, by Krauss and Bethke; and chemical v. biological assay in determining vitamin C in milk and other materials, by Krauss and Washburn.

Feeding and handling experiments on the Pusa pedigree Sahiwal herd (third report, 1934-35), W. SAYER (*Agr. and Livestock in India*, 7 (1937), No. 2, pp. 145-161, pls. 4, fig. 1).—Information is presented on the growth, production, and reproduction performance of a Sahiwal dairy herd during the third year of an intensive and carefully controlled program of feeding and management.

The problem of proving dairy bulls, S. TAUSSIG (*Internatl. Rev. Agr., Mo. Bul. Agr. Sci. and Pract.* [Roma], 28 (1937), No. 3, pp. 697-817, figs. 5).—This is a comprehensive review of various methods proposed for evaluating dairy bulls.

The influence of sunflower silage upon milk production, C. L. COLE, R. L. DONOVAN, and N. N. ALLEN (*Jour. Dairy Sci.*, 20 (1937), No. 5, pp. 221-230).—In an experiment conducted at the Minnesota North Central Substation, 14 high grade or purebred Guernsey cows freshening in the fall or early winter were divided into two similar groups. For one complete lactation period one of the groups received 3 lb. of sunflower silage daily per 100 lb. of live weight in addition to an adequate grain ration and all the alfalfa hay they would consume, while a second group received a like grain ration and a full allowance of alfalfa hay but no silage. During the succeeding lactation period these groups were reversed and continued through a second complete lactation. No silage was fed in the barn to either group during the pasture season, both lots having access to the same pasture. Thirteen cows completed the two lactations, and their records are included in the tabulation of data.

Based on the group averages for the two lactations, there was no apparent advantage in milk and butterfat production or in the health or condition of

the cows due to the inclusion of sunflower silage in the ration containing an abundant supply of legume hay and the cows having free access to water. Other studies indicated that under conditions existing in that locality alfalfa hay yielded more total digestible nutrients and a great deal more protein per acre than sunflower silage and could be produced with less than one-half the labor. It is concluded that it appears inadvisable to attempt to provide succulent feed in the dairy ration when conditions are such that it will add materially to the cost of milk production.

Permanent pasture studies, E. C. ELTING, J. P. LAMASTER, and J. H. MITCHELL (*South Carolina Sta. Bul. 308 (1937), pp. 54, figs. 12*).—Two lines of attack were employed in this study.

I. *The grazing value of Bermuda and of carpet grass pastures receiving various fertilizer treatments.*—In this phase of the study, five permanent pasture areas as described were grazed with milking cows and the worth of the pastures expressed in terms of their total digestible nutrient replacement value (alfalfa hay equivalent) based on the total nutrient requirements of the grazing animals for maintenance, live weight change, and milk production minus the nutrients supplied by supplemental feeding. During the course of the trials (1933-35) the average length of the grazing season was slightly under 200 days. The experimental pastures included an untreated Bermuda area, Bermuda pastures receiving ground limestone alone, limestone and superphosphate, and limestone and manure, and a carpet grass pasture receiving a limited amount of superphosphate. The average alfalfa hay equivalent yield per acre for these areas was 2.67, 3.55, 4.14, 4.29, and 2.14 tons, respectively. The average total amount of 4-percent fat-corrected milk produced was 7,405, 9,380, 11,434, 11,125, and 7,107 lb., respectively. The percentage of the total nutrient requirements of the animals supplied by the various pastures was 61, 62.1, 62.6, 63.5, and 48.9, respectively. Complete data on the fertilizer treatments of the pastures, carrying capacities, total milk yields, the amount of nutrients obtained from the pastures, and the net gain in value resulting from the various fertilizer treatments are presented in tabular form. Supplementary information on seasonal variations in the composition of the pasture herbage and the comparative composition of Bermuda and carpet grass are presented graphically.

II. *The effect of various pasture fertilizer treatments on the yields and the composition of Bermuda grass.*—This section of the report deals with the green yield and the composition of Bermuda grass receiving various fertilizer treatments as determined on 46 $\frac{1}{2}$ -acre plats clipped with a lawn mower at regular intervals over four growing seasons, 1929-32, and on 16 additional $\frac{1}{2}$ -acre plats over the 3-yr. period, 1930-32. The data presented include total green yields and dry matter yields for all plats, and the average composition of the herbage, seasonal trends in rate of growth and composition, and complete mineral analysis from selected plats. Summarizing the results, "rainfall is the most important factor in determining yields. When the rainfall is insufficient, there is little difference between the yields from the various treatments. As indicated by chemical composition, rapidly growing plants produce greater yields and have superior feeding value. The combination of limestone with superphosphate proved to be the most practical treatment made under the conditions of the experiment. The yield and the composition of the pasture herbage were influenced by the frequency of clipping. The results indicate that grazing pastures in such a manner as to permit the accumulation of 2 or 3 weeks' growth is favorable to large yields without adverse changes in the feeding value of the herbage. The feeding value of pasture herbage is lower during the latter part of the growing season because of changes in the chemical composition."

A method for obtaining arterial blood from the goat, W. R. GRAHAM, JR., C. W. TURNER, and E. T. GOMEZ (*Missouri Sta. Res. Bul.* 260 (1937), pp. 15, figs. 11).—This bulletin describes and illustrates a surgical method by which the carotid artery of the goat may be brought to the surface of the skin for use in the convenient sampling of arterial blood. This technic and one previously noted for obtaining arterial blood samples from cows (*E. S. R.*, 76, p. 530) have been employed in connection with a comparison of arterial and mammary bloods as related to milk secretion.

The nutritive value of raw and pasteurized milk for calves, G. S. WILSON, F. C. MINETT, and H. F. CARLING (*Jour. Hyg. [London]*, 37 (1937), No. 2, pp. 243-253, fig. 1).—This is a report of a calf-feeding experiment conducted in a healthy Shorthorn herd in which alternate calves as they were born were allocated to one of two groups, one of which received raw milk and the other pasteurized milk (145° F. for 30 min.) from 3½ days to 8 weeks of age at the rate of approximately 1 lb. per 10 lb. of live weight daily. The average increase in weight over the 8-week period was 53.72 and 53.86 lb. for the groups fed raw and pasteurized milk, respectively, with nothing in the results to suggest that the nutritive value of pasteurized milk for calves was in any way the inferior.

Proceedings of the twenty-ninth annual convention [of the] International Association of Milk Dealers: Laboratory and production sections (*Internatl. Assoc. Milk Dealers, Proc.*, 29 (1936), Lab. Sect., pp. 141, figs. 18; Prod. Sect., pp. 105, figs. 3).—At this meeting held in Atlantic City, N. J., October 12-14, 1936, the following papers were among those presented before the laboratory section: Discussion of *Esch. coli* Test to Determine the Efficiency of Pasteurization, by A. R. M. MacLean (pp. 3-9); The Grading of Raw Milk on the Basis of Bacterial Cleanliness, by G. S. Wilson (pp. 11-20); Factors Affecting the Viscosity of Market Cream, by H. B. Henderson (pp. 21-35); Proposed Changes in Standard Methods Medium and Temperature of Incubation, by A. J. Powers et al. (pp. 38-50); Report of Collaborator on Cooperative Work With Proposed Changes in Medium and Temperature of Incubation, by E. Kelly (pp. 50-75); Comments on Possible Influence of Variations in Laboratory Technique, by J. F. Cone (pp. 75-81); Differential Value of a Milk Medium Containing at Least Two Per Cent of Skim Milk, by C. N. Stark (pp. 82-85); Comparison of Potentiometric and Colorimetric Methods of Determining the Hydrogen Ion Concentration of Nutrient Agar, by J. S. Taylor (pp. 86-98); Sources of Milk Solids for Use in Modified Media, by A. Bradfield (pp. 94-100); Control of the Oxidized Flavor in Milk, by G. R. Greenbank (pp. 101-116); The Cause of Oxidized and Rancid Flavors in Raw Milk, by J. A. Anderson (pp. 117-134); and Flavors of Milk Influenced by Different Systems of Feeding Certain Roughages, by C. L. Roadhouse and J. L. Henderson (pp. 135-141).

The following papers were presented before the production section: Development of the Lactochrometer, by H. H. Tucker (pp. 42-44); Mastitis and Carbohydrate Deficiency, by G. W. Cavanaugh (pp. 45-54); Composition of Milk as Affected by Sub-clinical Mastitis, by A. C. Dahlberg, J. J. Kucera, J. C. Hening, and G. J. Hucker (pp. 54-67); The Significance of Bacterial and Chemical Changes Occurring in Mastitis Milk, by L. A. Burkey, E. B. Meigs, G. P. Sanders, and J. F. Cone (pp. 67-70); Mastitis Detection and Control, by R. B. Little (pp. 71-87); The Presence of Mastitis Streptococci in Bovine Mammary Tissue (Preliminary Report), by G. J. Hucker (pp. 87-92); and Bang's Disease Control, by L. J. Thompkins (pp. 99-105).

Papers and proceedings of the fourteenth annual conference of the New York State Association of Dairy and Milk Inspectors (N. Y. State Assoc. Dairy and Milk Insp., Ann. Rpt., 10 (1936), pp. 247, pl. 1, figs. 9).—The following papers, in addition to a number on mastitis noted on page 700, were presented at Schenectady, N. Y., on September 23–25, 1936: An Economic Comparison of Different Methods of Milk Cooling, by H. W. Riley (pp. 21–34); Comparison of Certain Tests Applicable to Raw Milk as Received at Plants, by S. Pincus, S. Abraham, and W. D. Tiedeman (pp. 35–55); The Resazurin Test for the Sanitary Condition of Milk, by G. A. Ramsdell (pp. 57–72); Investigation of the Amylase and Phosphatase Tests as an Indication of Pasteurization, by F. W. Gilcreas and W. S. Davis (pp. 73–94); Desirable Changes in Standard Media and Incubation Temperatures, by R. S. Breed (pp. 107–121); The Use of Skim Milk Agar in Detecting Proteolytic Bacteria Affecting the Quality of Milk, by C. N. Stark (pp. 123–126); Safer Milk and Infant Mortality in Schenectady, by J. H. Collins (pp. 127–129); The Use of Chlorine Solutions on the Dairy Farm, by H. W. Lehmkuhl (pp. 131–152); Vitamin C, Copper, and the Oxidized Flavor of Milk, by P. F. Sharp, G. M. Trout, and E. S. Guthrie (pp. 153–164); Controlling the Flavor of Pasteurized Milk, by H. J. Brueckner (pp. 165–170); and The Survival of *Streptococcus pyogenes* in Cheddar Cheese, by G. J. Hucker and J. C. Marquardt (pp. 171–174).

A study of the alkali-forming bacteria in raw milk [trans. title], W. Störck (*Zentbl. Bakt. [etc.]*, 2. Abt., 94 (1936), No. 14–18, pp. 295–330, figs. 2).—This is a report of a systematic study of various bacteria in milk which possess proteolytic properties with an accompanying production of an alkaline reaction. By plating various dilutions of milk in china blue lactose agar and incubating for 48 hr. at 30° C., the alkali-forming organisms were distinguishable by colonies surrounded by a clear area. These organisms were found to belong in order of frequency to the following groups: Micrococci, corynebacteria, mycobacteria, spore formers, streptococci, alcaligenes, fluorescens, proteus, and sarcinae. These organisms in milk may give rise to clotting of the milk through rennet action, to slime formation, and to undesirable flavors and odors. Certain of the groups, including the spore bearers and streptococci, exert lipolytic action, causing rancidity in butter. In some instances their presence in soft cheese may be beneficial, since they are salt resistant, grow at normal ripening temperatures, and cause a slow casein degradation.

Detection and significance of the coliform group in milk, I, II, M. T. BASTRAM and L. A. BLACK (*Food Res.*, 1 (1936), No. 6, pp. 551–563; 2 (1937), No. 1, pp. 21–26).—A series of studies from the Maryland Experiment Station is reported.

I. A comparison of media for use in isolation.—In this phase of the study five liquid and nine solid media were compared with reference to their efficiency in determining the presence of the coliform group of bacteria in milk. Many of the media proved unsatisfactory, certain ones yielding many false presumptive reactions or proving to be quite inhibitive as indicated by the number of positive samples, and none of the media tested were satisfactory in completely inhibiting the growth of organisms other than the coli-aerogenes group. Of the solid media, neutral red bile and violet red bile were the most satisfactory, and 2 percent brilliant green bile was the best liquid media for the isolation of the coliform group from raw, pasteurized, and certified milk. Both of the solid media exceeded the brilliant green bile in accuracy and in number of positive tests obtained, and violet red bile was somewhat better than the neutral red bile in the ease with which coli-aerogenes organisms were recognized. A medium pre-

pared in the Maryland laboratory is described which proved equal to the best of the other media tested. Formate-ricinoleate broth proved superior to eosin-methylene blue plates in the confirmation of positive presumptive tests.

II. *Identification of species isolated.*—A further study was made of the cultures isolated from various milks on different media as noted above. The 310 cultures of the *Escherichia-Aerobacter* group isolated from 331 samples of raw milk consisted of 57 percent *Escherichia*, including 12 species, *E. communior* predominating; 22 percent *Aerobacter* of 5 species with *A. hibernicum* predominating; and 21 percent intermediate of 5 species with *Citrobacter freundii* predominating. Only one of 34 pasteurized milk samples yielded *Escherichia-Aerobacter*. Of 15 cultures studied, one was *Escherichia*, one *Aerobacter*, and 13 intermediate, with *C. decolorans* predominating. Eight cultures were isolated from 25 samples of certified milk, including four *Escherichia*, three *Aerobacter*, and one intermediate. This group of organisms as a whole was more significant than any one genus or species in indicating contamination. No correlation was apparent between the different media used and the genus or species isolated.

The detection and significance of *Escherichia-Aerobacter* in milk.—III, *Correlation of total bacterial count and presence of the coli-aerogenes group*, M. T. BARTRAM and L. A. BLACK (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 105-112).—Continuing this study, 331 samples of raw milk, 31 samples of pasteurized milk, and 25 samples of milk meeting the requirements for certified milk were examined for total bacterial count by standard methods, and the coli-aerogenes groups were isolated on both liquid and solid media.

In the case of the raw samples the colon-positive samples showed an average total count 2.9 times that of the colon-negative lot, and less than 10 colon organisms per cubic centimeter were found in 69.2 percent of the samples having a total count of under 10,000 bacteria per cubic centimeter. In pasteurized samples the count of the colon-positive lot averaged 4.3 times higher than for the colon-negative samples, and no pasteurized milk with counts under 1,000 per cubic centimeter contained colon organisms. In no case were colon organisms found in 0.1-cc samples of certified milk. In a few cases where bacterial counts were made on tryptone glucose milk medium at 32° C., 93.5 percent of samples with counts under 10,000 were colon-negative, and counts on colon-positive samples were 12 times higher than on colon-negative samples. These findings are discussed in relation to suitable standards for determining the sanitary qualities of milk.

Streptococcus cremoris, E. S. YAWGER, JR., and J. M. SHERMAN (*Jour. Dairy Sci.*, 20 (1937), No. 4, pp. 205-212).—Studies at the [New York] Cornell Experiment Station of the physiological characteristics of 41 cultures of lactic acid producing streptococci identified as *S. cremoris* and 25 cultures identified as *S. lactis* by methods as described gave definite evidence that these species can be clearly differentiated and that *S. cremoris* is entitled to rank as a separate species. An extensive description of this organism is presented. *S. cremoris* can be separated from *S. lactis* by the inability of the former to produce ammonia in 4 percent peptone and by its inability to grow at 40° C. in the presence of 4 percent sodium chloride and in alkaline broth at pH 9.2. It is also generally less tolerant to methylene blue than *S. lactis*.

A study of oxidized flavor in commercial pasteurized milk, C. T. ROLAND, C. M. SORENSSEN, and B. WHITAKER (*Jour. Dairy Sci.*, 20 (1937), No. 4, pp. 215-218).—The findings relative to the flavor, fat content, and bacterial quality of 139 samples of commercial pasteurized milk from dairies in 19 different cities led to the conclusion that (1) oxidized flavor was the predominating off-

flavor noted and was present in 21 percent of the samples examined. (2) milk having oxidized flavor was generally higher in fat content and lower in bacterial count than milk free from this defect, and (3) premium milks generally high in fat and low in bacterial count had oxidized flavor much more frequently than standard grades of milk which were generally low in fat and of higher bacterial count.

Anti-rachitic cow's milk, W. E. KRAUSS and R. M. BETHKE (*Amer. Assoc. Med. Milk. Comms. [etc.], Proc.*, 25-28 (1932-35), pp. 256-259).—This brief report from the Ohio Experiment Station describes an experiment in which Holstein milk was fortified, either through the feeding of irradiated yeast to cows or by direct ultraviolet irradiation, so that the milk in each case contained approximately 55 Steenbock rat units of vitamin D per quart as assayed by the curative test with rats according to the standard line test procedure. Prophylactic assays of these milks definitely indicated that the fat from the irradiated milk was more potent, 40 mg of fat from this source being equivalent to 60 mg of fat from the yeast milk.

The effect of homogenization at different temperatures on some of the physical properties of milk and cream, R. WHITAKER and L. D. HILKER (*Jour. Dairy Sci.*, 20 (1937), No. 5, pp. 281-287).—Samples of 4-percent milk and 20-percent cream were homogenized at a pressure of 3,000 lb. per square inch at temperatures of 50°, 60°, 70°, 80°, 90°, 100°, 120°, 145°, and 175° F. Two samples were run at each of the seven lower temperatures, one sample being slowly heated from 40° to homogenization temperature while the other was heated to 145° and then rapidly cooled to homogenization temperature. All samples were pasteurized at 145° for 30 min. immediately after homogenization and aged for 18 hr. at 40° before testing. The results are presented on the effect of these various treatments on average fat globule size, fat globule clumping, cream volume, curd tension, and flavor of the milk samples, and on the average fat globule size, fat globule clumping, viscosity, feathering in hot coffee, skim milk layer, flavor, and color of the cream samples.

It is concluded that the butterfat in milk or cream must be liquid or in a relatively soft condition in order to obtain changes in the above-noted properties by homogenization. It is evident that the condition of butterfat in milk or cream immediately after adjusting to temperatures between 60° and 90° depends upon the temperature treatment of the product prior to its adjustment to these temperatures.

Testing milk and cream, D. H. NELSON (*California Sta. Circ. 340* (1937), pp. 19, figs. 12).—This circular, which supersedes Circular 230 (E. S. R., 46, p. 578), describes the procedure for conducting the Babcock fat test and the Mann acidity test on milk, skim milk, and cream; specific gravity determinations on milk and skim milk; and sediment tests on milk and cream.

The use of annatto as a denaturing agent in cream (*Maryland Sta. Rpt. 1936*, pp. XXIII, XXIV).—Data on the use of annatto (commercial cheese color) in a concentration of 1:20,000 for denaturing cream are briefly noted.

The oxidation of butterfat, I, II, V. C. STERNITZ and H. H. SOMMER (*Jour. Dairy Sci.*, 20 (1937), Nos. 4, pp. 181-196, figs. 4; 5, pp. 265-280, figs. 4).—These studies are reported from the Wisconsin Experiment Station.

I. The catalytic effect of light.—This phase of the study deals with the oxidation of butterfat in the absence of light, the catalytic effect of various sources of light, and the protective action of various wrappers. Samples of butterfat were subjected to a 200-hr. oxidation period in the dark, being held at 98.5° C. with air constantly bubbling through them. Peroxides were detected after 3 hr. and rose to a maximum at 104 hr., followed by an increase in volatile

acids. Peroxide formation was accompanied by a rapid bleaching of color until at 106 hr. only a trace of yellow color remained. The development of peroxides ordinarily preceded the appearance of tallowy flavor, although tallowy flavor was not always apparent at the same peroxide number. Ultraviolet light and sunlight exerted a very marked catalytic effect on the oxidation of butterfat, while diffused daylight gave a much slower and lamplight a very slow reaction. Infrared light caused no reaction during a 14-hr. exposure. Aluminum foil wrappers prevented the oxidation of butterfat and dark green or dark red transparent wrappers were quite effective in this respect, while other transparent wrappers gave a varying degree of protection, indicating that an effective transparent wrapper must exclude at least ultraviolet light and decrease transmission of the longer rays as much as possible.

II. *The composition of the fat in relation to its susceptibility toward oxidation.*—In this phase of the study the stability toward oxidation of butterfat samples, obtained from various sources, was measured, using an accelerated peroxide test. Other data reported include the color of the fat, refractive index, iodine number, thiocyanogen-iodine number, and the linoleic acid, oleic acid, and saturated fatty acid contents. Butterfat samples from individual cows indicated considerable variation in the stability of the fat toward oxidation from cows of different breeds, from individuals within a breed, and from the same individual at different times. Sufficient numbers were not run to establish definite breed differences, although milk from Holstein cows on winter ration was more susceptible to oxidation than that from the other breeds. Stability of butterfat toward oxidation is inversely related to the unsaturation of the fat, the fat from cows on grass is less saturated than that from cows on winter ration and hence is more susceptible to oxidation, with evidence that the linoleic acid content rather than the oleic acid content governs stability. It appears that the protective substances in milk increase when cows are on grass, thus preventing the development of oxidized flavor in spite of the low stability of the fat toward oxidation. Carotene content is unrelated to stability of the fat.

Yield of Cheddar cheese in relation to the fat percentage in milk, K. DESAI and S. Cox (Agr. and Livestock in India, 7 (1937), No. 2, pp. 162-170, pl. 1).—In a series of tests with milk ranging in butterfat content from 0.1 to 6.5 percent, it is shown that cheeses made from milk containing from 3.5 to 5 percent fat were the best, both from the standpoint of economy and quality. Under conditions existing in India cheese can be economically manufactured from such milk.

The microbiological flora on the surface of Limburger cheese, C. D. KELLY (Jour. Dairy Sci., 20 (1937), No. 5, pp. 239-246, figs. 8).—The New York State Experiment Station has studied the types and relative numbers of organisms found on the surface of Limburger cheese day by day throughout the ripening period, samples being obtained from 14 New York factories. The microbiological changes showed a very definite sequence with advance of the ripening period. Budding yeast cells appeared after 2 or 3 days and were very abundant in from 4 to 5 days, at which stage the surface of the cheese became slimy. Uniform distribution of the organisms in the slime over the surface was accomplished by rubbing the cheeses with the hands. Short slender rods (*Bacterium linens*) appeared about the sixth or seventh day, rapidly increased in numbers, and were uniformly distributed over the surface about the eighth day. Undoubtedly these organisms were responsible for the reddish color which appears on the cheese at this time. The slime on the surface also became heavier or thicker at this stage. Yeast cells decreased in size from the tenth to the eighteenth day and finally disappeared entirely. It is believed that other types of

organisms, while present from time to time, do not have any important part in the ripening of Limburger cheese.

Wrappers for processed cheese, H. L. TEMPLETON and H. H. SOMMER (*Jour. Dairy Sci.*, 20 (1937), No. 5, pp. 231-238).—The Wisconsin Experiment Station has studied various factors responsible for the discoloration of tinfoil wrappers on processed Cheddar cheese and has also made a comparison of the desirability of a number of wrappers, including commercial tinfoil, aluminum foils coated with certain protective materials to prevent corrosion, a rubber composition film, and a cellulose film. These wrappers were used on cheese samples made up with different emulsifying salts including sodium citrate, disodium phosphate (ortho), and tetrasodium pyrophosphate. The emulsifying salt and the acidity of the cheese are important factors governing tinfoil discoloration. The phosphate salts appear to accelerate the discoloration, especially when the reaction of the cheese-quinhydrone paste is more alkaline than pH 5.8. The metal foils proved superior to the other types of wrappers studied, and the opinion is expressed that for general use with all types of cheese tinfoil is probably more satisfactory than aluminum foil, although with certain types of cheese aluminum foil properly coated may offer distinct advantages.

VETERINARY MEDICINE

Clinical diagnostics of the internal diseases of domestic animals, B. MALKMUS, rev. by T. OPPERMANN. Eng. rev. by J. R. MOHLER and A. EICHHORN (*Chicago: Alexander Eger*, 1936, 11. ed., Eng. rev., pp. 312, pl. 1, figs. 71).—This is a revision from the latest English translation and eleventh German edition of the work previously noted (E. S. R., 69, p. 577).

Practical veterinary pharmacology, materia medica, and therapeutics, H. J. MILKS (*Chicago: Alexander Eger*, 1936, 3. ed., [rev.], pp. XIII+581. [pls. 3], figs. [30]).—In this third edition (E. S. R., 64, p. 555) the text has been carefully revised and made to conform with the U. S. P. XI. New sections have been added on the treatment of heart worms, the vitamins, and insecticides. The sections on respiratory stimulants, the barbitals—including the more recent and basal injection anesthetics, toxicology of prussic acid, the salicylates, local anesthetics, and preparations of the pituitary body have been largely rewritten. The chapter on biologics has been revised by A. Eichhorn.

Textbook of meat inspection, J. DRABBLE (*Sydney: Angus & Robertson*, 1936, pp. XV+353, figs. 47).—Three of the 20 chapters of this textbook deal with general pathological conditions, bacterial diseases, and parasites and parasitic diseases, respectively.

Fundamentals of bacteriology, M. FROBISHER, JR. (*Philadelphia and London: W. B. Saunders Co.*, 1937, pp. 474, figs. 230).—The first section of this work considers fundamental principles (pp. 17-97); the second section, the class Schizomycetes (pp. 98-259); and the third section, bacteria in relation to disease (pp. 260-455).

The anaerobe bacteria, M. WEINBERG, R. NATIVELLE, and A. R. PRÉVOT (*Les Microbes anaérobies. Paris: Masson & Co.*, 1937, pp. IV+1186, pls. 10, figs. 161).—Following a brief preface, the seven parts of this work deal with technic (pp. 1-117); Gram-positive central and subterminal spore pathogenic anaerobes (pp. 119-412); terminal spore anaerobes (pp. 413-515); Gram-positive slightly pathogenic or nonpathogenic anaerobes (pp. 517-655); Gram-negative anaerobes (pp. 657-884); cellulolytic, pectinolytic, and the *Clostridium butyricum* group of anaerobes (pp. 885-962); and anaerobic cocci (pp. 963-1036). Anaerobic spirochetes of the mouth, bronchi, and lungs (pp. 1037-1042), other anaerobic

microbes (p. 1043), and the habitat of the anaerobes (pp. 1045-1052) are dealt with, and an index of the anaerobes described or mentioned in the volume (pp. 1053-1061), a bibliography arranged by subjects, and a table of contents are included.

Dictionary of the bacteria pathogenic for man, animals, and plants, P. HAUDUBOX, G. EHRLINGER, A. URBAIN, G. GUILLOT, and J. MAGROU (*Dictionnaire des bactéries pathogènes pour l'homme, les animaux, et les plantes. Paris: Masson & Co., 1937, pp. 597*).—Following a preface and discussion of bacteriological nomenclature, including the international rules of botanical nomenclature by B. P. G. Hochreutiner (pp. 7-19), this work deals with the pathogenic bacteria, the arrangement being alphabetical by genera and species. A brief characterization given of each genus, together with an indication of the type species and the morphology, is followed by the cultural characteristics and biochemical and biological properties of each of the species. A list of the forms recognized as belonging to the genus *Salmonella* (44 in number), their synonymy, and tables showing (1) the important biochemical properties of the forms of *Salmonella*, (2) antigenic constituents of the forms of *Salmonella*, (3) differential reactions of the intestinal pathogens, (4) classical serological reactions of the species of (a) *Escherichia* and *Salmonella* and (b) *Shigella*, and (5) classification of the streptococci are appended. Five infolded tables summarize the biological characteristics of the genera *Aerobacter*, *Alcaligenes*, *Escherichia*, *Proteus*, *Salmonella*, and *Shigella*, and permit of their identification.

[**Work in animal pathology and bacteriology at the Maryland Station**] (*Maryland Sta. Rpt. 1936, pp. XXIX-XXXII, XLI, XLII*).—Notes are given (E. S. R., 74, p. 694) on the progress of livestock disease projects under way, including blackhead in turkeys (E. S. R., 75, p. 849), so-called "running fits" in dogs, and equine encephalomyelitis. Work on the inheritance of disease resistance in poultry is also referred to.

[**Report of animal disease investigations by the Ohio Station**] (*Ohio Sta. Bul. 579 (1937), pp. 93-97*).—Work of the year in animal pathology and parasitology referred to (E. S. R., 75, p. 397) includes the results of rapid whole blood pullorum tests in chicks and pseudorabies (mad itch) transmission, both by B. H. Edgington and N. A. Frank; fowl paralysis and parasitic examination of lambs, both by [C. A.] Woodhouse and R. E. Rebrassier; immunity experiments in avian coccidiosis, by Rebrassier and Woodhouse; and crystal violet vaccine for prevention of hog cholera, by Edgington and A. J. Schalk.

Concepts and mechanisms of resistance in helminthic infections, T. W. M. CAMERON (*Canad. Jour. Res., 15 (1937), No. 4, Sect. D, pp. 77-90*).—It is pointed out that while the relations that exist between the helminths and their hosts cannot be divided into specific groups, it is desirable that some classification of these relations, together with clear-cut definition of terms, be widely accepted in order that the subject may be discussed intelligently. Thus "a tentative classification is suggested, which distinguishes between (1) compatibility and incompatibility, which refer only to the host environment as it exists before invasion by the parasite; (2) resistance, of various kinds and degrees, which refers to the reaction of the environment to the presence of the helminth; and (3) tolerance and intolerance, which refer to the reaction of the environment to the effects of the helminth."

Modifying the quantitative character of coccidian infection through a dietary factor, E. R. BECKER and N. F. MOREHOUSE (*Jour. Parasitol., 23 (1937), No. 2, pp. 153-162*).—Experiments conducted on rats raised in the laboratory and known to have been free from accidental infection up to the date of experi-

mental infection with *Eimeria mizairii* are said to have shown that diet bears a very close relationship to the severity of coccidian infection.

An increase in the proportion of basophilic leucocytes in guinea pigs experimentally infected with swine lungworms, D. A. PORTER (*Jour. Parasitol.*, 23 (1937), No. 1, pp. 73-82, figs. 3).—The blood cell reaction of the swine host experimentally infected with lungworms (*Metastrongylus clongatus*) is reported upon, particular attention being called to the marked increase in the percentage of circulating basophilic leucocytes or basophiles in such guinea pigs.

The data presented indicate that the increase in the percentage of basophiles is probably related to the development of the worms in the lungs. Basophiles first appear when the worms reach the lungs, increase in number as the worms develop, and finally return to normal when or after the parasites apparently leave the lungs.

Cysticercosis bovis and its prevention, W. J. and H. B. PENFOLD (*Jour. Helminthol.*, 15 (1937), No. 1, pp. 37-40).—This contribution is presented with a view to emphasizing the fact that the economic waste caused by *Taenia saginata* on sewage farms is quite unnecessary, and that cattle can be readily immunized so that there is no human risk of infection from the flesh of such cattle. Large doses, usually 400,000 in number, of fresh eggs of *T. saginata* were given by mouth in immunizing the cattle against *Cysticercus bovis*. Attempts to produce a secondary infection from 54 weeks to 23 mo. after the primary infection by administering large doses of fresh eggs invariably failed, the cattle having become immune.

Studies on the cercaricidal property of the sera of vertebrate animals, M. A. TURANGUI and V. A. MASILUNGAN (*Philippine Jour. Sci.*, 60 (1936), No. 4, pp. 393-398).—In tests made to determine the cercaricidal property of the serums of different kinds of vertebrates against two species of larval trematodes, namely, the *Schistosoma japonicum* and *Cercaria matimensis* Tubangui 1928, all of the serums tested, except those of the cat and the rabbit, possessed marked cercaricidal action against the cercaria of *S. japonicum*. With *C. matimensis*, the effect was only partial.

Resistance to helminth parasites in domestic animals, J. D. MIZELLE (*Vet. Med.*, 32 (1937), No. 4, pp. 168-170).—This contribution is presented with a list of several references to the literature.

A further note on the incidence of anthrax in stock in Australia, M. HENRY (*Austral. Vet. Jour.*, 12 (1936), No. 6, pp. 235-239).—This contribution supplements the earlier account (E. S. R., 33, p. 279).

A new disease of veld rodents: "Tiger River disease", J. H. HARVEY PIER (*So. African Inst. Med. Res. Pubs.*, No. 20 (1927), pp. 163-186, pls. 2).—The name *Listerella hepatolytica* n. g. and sp. is proposed for the causative organism (a Gram-positive motile bacillus) of an undescribed fatal bacterial disease of the gerbil (*Tatera lobengulae*), a small ratlike animal which burrows in the ground in the Tiger River district of the Union of South Africa. "Experimentally, this organism has been found to be highly pathogenic for all the small veld rodents tested and also for house mice. For rats, guinea pigs, rabbits, and the larger veld rodents its pathogenicity is less or nil. For cats, dogs, and monkeys it is nonpathogenic. Infection can be produced by subcutaneous inoculation or by feeding, and it is thought that it is by feeding that the disease is spread in nature. The chief lesions produced by the organism are intestinal ulceration (when infection is by feeding), necrosis of the liver and spleen, and bacteremia."

Pathogenic organisms of the genus *Listerella*, C. V. SEASTONE (*Jour. Exptl. Med.*, 62 (1935), No. 2, pp. 203-212, pls. 2, figs. 2).—The cultural and serological

properties of closely related Gram-positive organisms that have been isolated by different observers from meningitis in man, encephalitis in cattle and sheep, a myocardial infection in fowl, and a general infection in rabbits, and apparently belong to the genus *Listerella*, are described. When injected intravenously into chickens, rabbits, or guinea pigs there is an unusual blood response, the monocytes being markedly increased. The organisms tend to localize in the myocardium with resulting necrosis.

Ovine encephalomyelitis associated with *Listerella* infection, E. JUNGHERS (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 1, pp. 73-87, figs. 8).—The loss of several of the best animals in a flock of some 200 purebred sheep maintained for teaching and demonstration purposes at the Connecticut State College from an affection characterized by cerebral symptoms led to the investigation at the [Connecticut] Storrs Experiment Station here reported. Following the discovery of distinctive histologic lesions in the brain of these cases, an organism of the genus *Listerella* was isolated which was capable of producing a pathologic picture in experimentally injected animals that resembled the original. It is pointed out that similar cases in sheep have been reported by Seastone in the United States, as above noted, and by Gill in New Zealand under the name of circling disease as noted below.

"Pathologically the disease was characterized by affecting well-nourished mature animals of both sexes, by normal differential leucocyte count of the blood, slight parenchymatous and fatty changes in the liver, and centrally located polynuclear foci and monocytic perivascular and meningeal infiltration in the medulla oblongata. Disturbances similar to those observed in the sheep were produced in mice by intranasal injection of brain suspensions and of small doses of culture after an incubation period of about 2 weeks. Filtered brain material was innocuous, while large doses of culture administered by the same route produced a rapidly fatal septicemia and meningitis. Sheep infected with the cultured organism by intranasal or conjunctival application showed a marked thermic and agglutinative response and recovered. A similar but slighter reaction was observed in a control animal kept in the same pen. Intracarotid injection of sheep caused death from hemorrhagic meningitis within 48 hr.

"Two ovine *Listerella* strains isolated from the outbreak were found to be indistinguishable by cultural, agglutination, and agglutinin-absorption tests from one ovine and two human stock strains. Although the pathogenesis of the ovine disease is not entirely understood, it appears that the *Listerella* genus plays an important role as an etiological agent."

Ovine bacterial encephalitis (circling disease) and the bacterial genus *Listerella*, D. A. GILL (*Austral. Vet. Jour.*, 13 (1937), No. 2, pp. 46-56, fig. 1).—A further study (E. S. R., 69, p. 858) of the small Gram-positive organism commonly found by histological examination in the lesions of the midbrain of affected sheep, known locally in New Zealand as circling disease, has resulted in placing it in the genus *Listerella*, erected by Pirie in 1927 (see p. 696). The name *L. ovis* is suggested. It appears that the organisms of this genus have a wide range of pathogenicity, having already been found responsible for mortalities in rabbits, guinea pigs, gerbils, fowls, sheep, cattle, and man.

The treatment of piroplasmosis (*P. bigeminum*) with akiron, J. LEEG (*Austral. Vet. Jour.*, 13 (1936), No. 6, pp. 227-230).—Doses of 4-5 cc of a 5-percent solution of akiron (an N,N' (bis-methyl-chinolylium-methylsulfate-6) compound with urea), when given intravenously to cattle reacting acutely to *Piroplasma bigeminum* have been found to be followed by a rapid reduction in the number of parasites, a fall of temperature, and recovery of the animals. Animals so treated may rapidly lose their infectivity and thereby become again susceptible

to subsequent infection. The problem of determining a dose suitable for the avoidance of undesirable results in premunization, i. e., complete destruction of the blood parasites, remains for subsequent investigation.

Rinderpest studies, M. M. ROBLES (*Philippine Jour. Sci.*, 60 (1936), No. 4, pp. 361-385, figs. 15).—This contribution considers antirinderpest immune and hyperimmune serums, the serum of vaccinated animals and the effect of virus on its potency, and the spleen and lymph glands of rinderpest-recovered animals for immunization. A list is given of 20 references to the literature.

Immunity in rinderpest-vaccinated animals, T. TOPACIO and M. M. ROBLES (*Philippine Jour. Sci.*, 60 (1936), No. 4, pp. 387-392).—Experimental evidence was obtained to show that the lymph glands of rinderpest-vaccinated cattle and carabaos possess the ability of neutralizing the rinderpest virus in vivo. It is pointed out that this may be taken as a measure of the degree of general immunity produced in the animal body.

Alum-toxoid as a vaccine for the prevention of tetanus in animals, D. T. OYER, C. W. ADEY, and M. KENNEDY (*Austral. Vet. Jour.*, 12 (1936), No. 6, pp. 221-225).—The injection of alum-precipitated tetanus toxoid into a total of 30 horses caused a local edema of considerable size. This disappeared in about 4 days, giving place to a small firm swelling which might take some weeks, or even months, completely to resolve. One injection of 0.1 cc alum toxoid prepared from a toxin containing approximately 40,000 guinea pig m. l. d. per cubic centimeter protected guinea pigs against at least 30 m. l. d. of tetanus toxin. One dose of the same alum toxoid injected into a group of 20 horses stimulated a high antitoxic response. When 5 of these 20 vaccinated horses, together with 5 unvaccinated controls, were subjected to injection of toxin-free tetanus spores and calcium chloride solution, the vaccinated horses remained unaffected. Three of the controls developed tetanus and were destroyed.

A histological study of bovine udder parenchyma, G. O. HOLM (*Vet. Med.*, 32 (1937), No. 4, pp. 163-167, figs. 8).—This contribution is presented with a list of 22 references to the literature.

The significance of suspicious agglutination reactions for Bang's disease, C. P. FITCH, L. M. BISHOP, and W. L. BOYD (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 1, pp. 22-47).—Some of the past and present policies in regard to the diagnosis of Bang's disease in cattle the reactions of which are in the lower dilutions of the agglutination test, are first reviewed in this contribution from the Minnesota Experiment Station. A discussion of reactions in low dilutions due to ascending titers and to descending titers, and reactions in low dilutions only, is followed by a report of experimental work, presented at length in tables.

During the course of this work three individuals from the suspicious groups of animals became positive to the agglutination test. "Two of them aborted, and *Brucella abortus* was isolated from the placenta and colostrum. Two had been previous reactors, with titers above 1:100. The other individual gave a maximum titer of an incomplete at 1:100 approximately 1 yr. before she showed a higher titer and aborted. All three gave definite evidence by the blood test of infection in ample time to be removed from the herd before any of them aborted. *B. abortus* was not isolated by any bacteriological examination made of suspicious animals in the herd. None of the control animals have become infected, although some of them have developed titers of 1:50 and at times 1:100."

The study is considered to have shown that it is possible, through careful selection and study, to arrive at a reasonably accurate diagnosis and disposition of particular individuals showing suspicious reactions to Bang's disease.

"A definite rule for the disposition of all animals having suspicious titers for Bang's disease on a single test is impossible. It is necessary to have the results of a series of tests over a considerable period of time and information on the duration of pregnancy along with an adequate herd history in order that the proper deductions can be made. The results so far obtained show conclusively that most animals having a constant suspicious titer for Bang's disease are not dangerous and will not spread Bang infection in an otherwise clean herd."

The contribution is accompanied by a list of 44 references to the literature.

The double intradermal test (Holthum's technique) as an additional aid in the diagnosis of contagious abortion, T. LE Q. BLAMPIED and A. A. MACKAY (*Vet. Jour.*, 93 (1937), No. 5, pp. 178-188).—In the tests made, the details of which are presented in seven tables, the double intradermal test for infectious abortion was found to be of exceptional value in the eradication of the disease from a herd containing individuals whose serum furnished an indefinite reaction to the agglutination test.

The effects of exposure to different degrees of temperature on the etiological agents of bovine anaplasmosis and piroplasmosis, C. W. REES (*Jour. Parasitol.*, 23 (1937), No. 2, pp. 175-182).—It was found in the course of immunization experiments with anaplasmosis that *Anaplasma marginale* was not killed by exposure for 18 hr. at -78.6° C. and subsequent thawing at room temperature. The incubation period was lengthened but the virulence of the organism was not otherwise reduced. "None of five bulls was immunized as a result of one or more injections of red blood cells in which the etiological agent of anaplasmosis was killed by heat, whether this agent was present alone or mixed with the killed agents of piroplasmosis. All of the bulls contracted fatal infection of anaplasmosis when subsequently injected with the living agent. In heavily infected red blood cells from a clinical case of anaplasmosis, some of the etiological agent of this disease survived in vitro for about 20 min. during which the temperature of the cells was being raised from about 25° to 60° . In all other tests this agent was killed at 60° and also at 57° and 54° . In two tests it survived at 50° ; in two tests it was killed at 48° , but in three tests it survived at 48° . In one case of survival at 60° the etiological agent of anaplasmosis showed loss of virulence; in all cases of survival at temperatures lower than 60° the incubation period was lengthened but the virulence was not otherwise reduced. In one case, after an incubation period of 36 days, anaplasmosis was transmitted by cells drawn from the 'donor' during the incubation period and heated at 48° for 15 min.

"*Babesia argentina* and *B. bigemina* were killed in cells heated 10 min. in a bath at 48° , and *B. bigemina* at all temperatures higher than 48° ; they both survived at 45° . The differential between the thermal death points of the etiological agents of anaplasmosis and piroplasmosis has furnished the basis of a practicable method of separating the two infections. The virulence of *B. bigemina* was greatly reduced by heating for 15 min. at 45° ."

Cross-immunity tests between *Anaplasma centrale* (South Africa) and *Anaplasma marginale* (Australia), J. LEGG (*Austral. Vet. Jour.*, 12 (1936), No. 6, pp. 230-233).—In the experiments reported it was found that while Australian cattle react fairly severely to *A. centrale* (South Africa) infection no fatalities occurred and the animals rapidly recovered. The individual resistance of *A. centrale* carriers to *A. marginale* (Australia) infection varies. Generally speaking, it is high. When cattle are preimmunized by inoculation with *Piroplasma bigeminum* and *A. centrale*, no untoward effects have followed their transfer from clean country to tick-infested pastures.

[Contributions on bovine mastitis] (*N. Y. State Assoc. Dairy and Milk Insp., Ann. Rpt., 10 (1936), pp. 95, 97, 98, 100-102, 104, 195-211, 213-236, figs. 2*).—The contributions on bovine mastitis presented at the fourteenth annual conference of the New York State Association of Dairy and Milk Inspectors held in Schenectady in September 1936 are as follows: Hemolytic Streptococci in Milk, by J. M. Sherman (pp. 95, 97, 98, 100-102); Composition of Milk as Affected by Subclinical Mastitis, by A. C. Dahlberg, J. J. Kucera, J. C. Hening, and G. J. Hucker (pp. 195-204), and The Significance of the Cell Count in Milk, part 1 by R. S. Breed (pp. 205-211) and part 2 by G. J. Hucker (pp. 213-220), both contributed from the New York State Experiment Station; The Pathological Changes in the Udders of Cows With Marked Physical Cases of Mastitis, by W. T. Miller (pp. 221-226); and How Mastitis Has Been Controlled in New York State Dairy Herds, by D. H. Udall (pp. 227-233).

Subcutaneous and cutaneous lesions in cattle which sometimes cause hypersensitiveness to tuberculin (so-called "skin tuberculosis"), G. B. Brook (*Vet. Jour., 93 (1937), No. 4, pp. 135-141, pl. 1, fig. 1*).—Following a brief introduction, presenting the clinical picture and the macroscopic and microscopic appearance, the incidence and distribution of the affection are considered.

Enterotoxaemic jaundice of sheep and cattle.—A preliminary report on the aetiology of the disease, A. L. ROSE and G. EDGAR (*Austral. Vet. Jour., 12 (1936), No. 6, pp. 212-220, figs. 2*).—A brief description is given of a fatal disease of sheep and cattle, associated with hemoglobinemia and hemoglobinuria, of which an intense icterus is the outstanding characteristic. "A hemolytic toxic bowel filtrate has been recovered from cases in both sheep and cattle. An organism morphologically and culturally resembling *Clostridium welchii* is readily cultivable from the small intestines of cases of the disease in both sheep and cattle. These organisms evince hemolysis when suitably incubated on blood agar plates. *C. welchii*, type A, antiserum protected mice against lethal doses of whole culture and type D antiserum did not. Calves protected with *C. welchii*, type A, antiserum were effectively protected against natural infection, control animals dying of the disease. . . . It is considered that there is sufficient evidence on which to base the opinion that the disease under investigation is an enterotoxaemia with *C. welchii*, type A, as the pathogen. In view of this and on account of the associated icterus, we propose the name of enterotoxaemic jaundice for the disease."

Summary of sheep diseases, E. T. BAKER (*Vet. Med., 32 (1937), No. 6, pp. 295-300*).—Replies received from the State veterinarian or other representative in the United States, Hawaii, and Canada regarding the sheep diseases of importance are presented.

Alum-vaccine as an antigen for the prophylactic immunization of sheep against black disease, D. T. OXER (*Austral. Vet. Jour., 13 (1937), No. 1, pp. 3-15, fig. 1*).—A description is given of a rapid test that has been developed for the determination of the antigenic value of *Clostridium oedematiens* toxoid.

"The conditions required to effect maximum precipitation of toxoid by means of potash alum, with minimum volume of resultant precipitate, were found to be a concentration of 2 percent, a pH value of 6.5 to 7.8, and an initial temperature of 37° C. The antitoxic response, in guinea pigs, to standard *C. oedematiens* vaccine (anaculture) was greater when the quantity was administered as two doses than when it was given as one dose. Half the quantity of vaccine, together with 2 percent potash alum, given as one dose, was more effective than the quantity of vaccine alone given as two doses. Vaccination experiments in groups of sheep confirmed the results obtained in guinea pigs in demonstrating the superiority of alum-precipitated vaccine.

The latter stimulated a response which was not only much greater but was also sustained at a much higher level than that following the use either of one or two doses of stock vaccine."

The production of artificial immunity against hydatid disease in sheep. E. L. TURNER, E. W. DENNIS, and D. A. BERBERIAN (*Jour. Parasitol.*, 23 (1937), No. 1, pp. 43-61, figs. 16).—This contribution deals with the experimental immunization of sheep against the larval stage of *Echinococcus granulosus*. The antigen employed was prepared from viable scolices and germinating membrane from fertile cysts of the lungs and livers of both sheep and cattle. Following the completion of the injections of antigen, intervals of from 21 to 170 days were allowed before attempts were made to infect the animals. It was found that the immunizing procedure did not prevent infection. Immunization reduced the number of cysts, as compared with controls, only in certain experiments. There were no significant differences in antibody content of immunized and control sheep under the stimulus of infection. In all experiments immunized animals have shown marked ability to defend themselves against the growth of the parasites by a rapid and highly efficient walling off of the invaders. The greatly thickened adventitia and thorough calcification of the wall of the hydatid cyst at an early period produce an efficient and eventually impermeable mechanical barrier, leading to death of the parasite as the result of starvation and the accumulation of toxic metabolites.

A list is given of 32 references to the literature.

On the incidence of abomasal parasites in fat lambs from the same flock. A. H. H. FRASER and D. ROBERTSON (*Jour. Helminthol.*, 15 (1937), No. 1, pp. 53-60).—The authors found that a lamb slaughtered fat before or shortly after weaning and presumably healthy may contain up to 2,100 *Haemonchus contortus* and up to 4,670 *Ostertagia circumcincta*. Infestation with the former is negligible until August, but with the latter infestation remains almost steady from early May until mid-September. Infestation with *Trichostrongylus axei* occurs from May until mid-September but is never very heavy. The evidence obtained suggests, but does not prove, that in midsummer there is a wide difference in the infestation of single and twin lambs. It is pointed out that while the results obtained, so far as they relate to the seasonality of infestation, apply only to the flock of the Duthie Experimental Stock Farm, they are probably true for the northeast area of Scotland.

Diseases of the joints of swine. H. C. H. KERNKAMP (*Vet. Med.*, 32 (1937), No. 3, pp. 108-111, figs. 2).—A practical account.

Porcine brucellosis. F. M. HAYES (*Vet. Med.*, 32 (1937), No. 3, pp. 112-116, figs. 5).—A practical account.

Strangles in hogs. I. E. NEWSOM (*Vet. Med.*, 32 (1937), No. 3, pp. 137, 138, figs. 2).—In this contribution from the Colorado Experiment Station a brief report is made of a condition that developed in a lot of 30 hogs at Julesburg, Colo., characterized by abscesses in the region of the throat and found to be due to a hemolytic streptococcal infection.

The effect of feeding paradichlorobenzene-treated corn to swine. M. W. EMMEL and W. W. HENLEY (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 1, pp. 59-63).—In experiments conducted at the Florida Experiment Station it was found that the meat of pigs which had been fed for 15 days upon paradichlorobenzene-treated corn was distasteful and unfit for food. "The length of time required for the meat to become edible after a 15-day period on treated corn was approximately 62 days. After a 28-day period on treated corn this period was approximately 85 days. Cloudy swelling of the heart, kidney, and liver was the

only macroscopic lesion observed. Microscopic lesions consisted chiefly of cloudy swelling in all of the parenchymatous organs and involuntary muscle."

Transmission of the virus of equine encephalomyelitis by *Aedes taeniorhynchus*. R. A. KELSEY (*Science*, 85 (1937), No. 2198, p. 178).—Studies conducted in the Canal Zone are said to have proved definitely that *A. taeniorhynchus* can transmit the western type of equine encephalomyelitis from guinea pig to guinea pig. Tests of the transmission of the eastern type of the virus by the mosquito have thus far proved vain.

Losses of undetermined cause following an outbreak of equine encephalomyelitis. H. MABSE (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 1, pp. 88–93).—The author has been led to conclude that the acute and fatal disease which occurred following the 1936 epidemic of equine encephalomyelitis in Montana was probably not simply a second outbreak of the disease in horses in which no permanent immunity had been established, since it has been impossible to recover the virus of encephalomyelitis from these cases or to demonstrate the lesions in the central nervous system.

Etiology of kumri.—A preliminary note, P. G. MALKANI (*Indian Vet. Jour.*, 10 (1933), No. 1, pp. 6–19, pls. 4).—Kumri is a serious chronic disease of horses characterized chiefly by loss of strength in the hind legs and defective coordination between the various groups of muscles, which is prevalent in India, China, and the Federated Malay States and is most common in imported horses. The Indian breeds are relatively resistant. The schistosomiasis theory is considered the most plausible, since it explains all the known features of the disease.

"Kumri".—Second progress report, P. G. MALKANI (*Indian Jour. Vet. Sci. and Anim. Husband.*, 7 (1937), No. 1, pp. 1–7).—Kumri is considered a definite morbid entity since the majority of affected animals present a uniform symptom complex. Schistosomes have been found present in numbers in the liver of every case.

Experimental studies on the curative treatment of surra in native horses in the Philippines. II, L. M. YUTUC (*Philippine Jour. Sci.*, 61 (1936), No. 4, pp. 401–414).—This continuation of the contribution previously noted (II, S. R., 72, p. 535) reports upon experiments aimed at the determination of the value of the simultaneous intrathecal and intravenous injections of naganol and the combination of etharsanol and naganol treatment in relapsed animals.

"Of the seven horses employed in the intrathecal-intravenous method, four were able to stand the complete course of the treatment with the exception of one which received only two injections, but all four relapsed. Of the remaining animals two died in the course of the treatment and one was killed in extremis at the end of the post treatment observation period covering 24 days. In view of the above, the intrathecal-intravenous injections of naganol as a treatment of experimental surra in Philippine horses was found to be of not much value and to some extent attended with danger.

"The three animals subjected to the etharsanol-naganol treatment recovered. In declaring these cases recovered, animal inoculation, complement-fixation test, duration of post treatment observation, microscopic examination of the blood, increase in weight, and good condition of the animals were considered."

[Contributions on diseases and parasites of poultry] (In *Wissenschaftliche Berichte des VI. Weltgeflügelkongresses, 1936. Leipzig: Reichsmin. Ernähr. u. Landw.*, 1936, vols. 1, pp. 1–9, 86–115, figs. 7; 2, pp. 94–182, 271–273, figs. 2; 3, Eng., Ger., Fr., Ital., Span. abs. pp. 63–66, 88–99, 349–447, 522–524; Eng. Summaries, pp. 1, 2, 7–10, 63–78, 93).—Contributions relating to diseases and parasites presented at the Sixth World's Poultry Congress (II, S. R., 73, p. 246), held at Berlin and Leipzig, July 24 to August 2, 1936, include the following:

Vol. 1.—International Efforts and Prescriptions of Veterinary Police in Relation to Infectious Poultry Diseases, by H. C. L. E. Berger (pp. 1-9); Infectious Diseases of Hens and Their Treatment, by H. Miessner and R. Berge (pp. 86-94); Virus Diseases of Chickens, by J. R. Beach (pp. 95-103); The Significance of Poultry Diseases in the Control of Foodstuffs, by K. Beller (pp. 104-109); and The Genetics of Some Hereditary Rabbit-Diseases Compared With Similar Human Diseases, by H. Nachtsheim (pp. 110-115).

Vol. 2.—The Occurrence of Poultry Enteritis in Turkey [Anatolia], by S. T. Aygün (pp. 94-96); Observations Concerning the Advisability and Possibility of Isolation Methods in Poultry Raising as Aiding in the Prevention of the Spread of Contagious Diseases, by Baratte (pp. 96, 97); Researches on Etiology and Occurrence of Paralysis in Poultry in Austria, by R. Baumann (pp. 98, 99); Epidemic Tremors (Trembling Chick Disease), by C. A. Bottorff, A. E. Tepper, C. L. Martin, T. B. Charles, F. D. Reed, R. C. Bradley, T. G. Phillips, and S. R. Shimer (pp. 99-103), contributed from the New Hampshire Experiment Station (E. S. R., 76, p. 854); Livability Results in Chicks From Flocks Tested for Pullorum Disease by the Standard Tube Agglutination Method, by J. T. Burriss and E. W. Roberts (pp. 104-108); Observations on Fowl Paralysis (Lymphomatosis), by T. Dalling and G. H. Warrack (pp. 108-114) (E. S. R., 76, p. 854); Marek's Chicken Paralysis (Neurolymphomatosis), by J. Dobberstein (pp. 114-116); Practical Experiences in Combating Chicken Paralysis, by K. Fritzsche (pp. 116-118); The Importance of Paralysis and Leucosis in Poultry Raising, by L. Geurden (pp. 118-122); Treatment of Contagious Pip in Fowls With Argyrol, by E. A. Gutiérrez (p. 122); Poultry Tuberculosis, Its Prophylaxis and B. C. G. Experiments for Rendering Poultry and Pigeons Immune, by R. Harnach (pp. 123-125); The Importance of Veterinary Sanitary Control of Poultry-Breeding Establishments for Combating the Most Important Diseases, by H. Hartwig (pp. 125-128); Observations on Combating Diseases of Poultry in Holland, by B. J. C. te Hennepe (pp. 128-132); The Occurrence of Harmful Bacteria in Foodstuffs Caused by Poultry and Poultry Products, by [M.] Lerche (pp. 132-136); Paratyphoid of Pigeons, by G. Lesbouyries (pp. 136-138); Recent Advances in Research on Poultry Diseases, by C. A. McGaughey (pp. 138-141); New Experiences With Fowl Cholera, by R. Manning (pp. 141-146); Lack of Vitamins and Infections: A Disease of Ducks With Symptoms of Both Conditions, by C. Arroyo Martín and R. Campos Onetti (pp. 146-149); The Infectious Laryngotracheal Bronchitis of Fowls in Spain, by C. Arroyo Martín (pp. 150-155); Studies of Perosis in Chicks, by H. I. Milne (pp. 155-158); A Few Experimental Hints on Vaccination Against Laryngotracheitis, by N. Nakamura (pp. 158, 159); The Effects on Poultry of Certain Substances Commonly Employed for Therapeutic or Prophylactic Purposes or Used in Agriculture for the Combating of Injurious Insects, by A. Scaccini (pp. 159-162); Enteritis Infection in Fowls (Paratyphosis, Salmonellosis), by J. Schaaf (pp. 162-166); Poultry Paralysis and Diseases Due to Improper Feeding, by O. Seifried (pp. 166-169); Brachylaemi as the Cause of Hemorrhagic Appendicitis Among Poultry, by C. Sprehn and U. Maskar (pp. 169-172); The Importance of Bacillaemia Occurring With Tuberculosis of Chickens, by V. C. Tomescu (pp. 173-175); Notes on Poultry Tuberculosis in Lombardy, by G. Vianello (pp. 175-177); Investigation of the Intermediate Host of the Poultry Tape Worm as Found in Germany, by R. Wetzel (pp. 177-180); The Immunogenetic Value of the Cultural Forms of *Pasteurella avicida*, by V. Wynohradnyk (pp. 180-182); and Diseases Peculiar to Rabbits and Their Pathology, by O. Seifried (pp. 271-273).

[Work in avian pathology] (*Nulaid News*, 14 (1937), No. 11, pp. 45, 46, 63).—The work of 1936 in the poultry pathological laboratories, California State Department of Agriculture, is reported upon by H. A. Hoffman and E. E. Jones.

Filterable virus diseases of fowls, C. A. BRANDLY (*Vet. Med.*, 32 (1937), No. 4, pp. 180–182, fig. 1).—A summary of information, particularly on the pathogenic effect and differential diagnosis of leukemia and fowl pox, with control measures.

On some lesions associated with helminths in birds of economic importance, P. A. CLAPHAM (*Jour. Helminthol.*, 15 (1937), No. 1, pp. 49–52).—A report of studies conducted at the Institute of Agricultural Parasitology at St. Albans, England.

Infectious bronchitis, F. R. BEAUDETTE (*Ioica Poultry Impr. Assoc. Yearbook*, 5 (1937), pp. 99, 101, 102).—A practical summary on infectious bronchitis, a new respiratory disease previously noted (E. S. R., 76, p. 696), contributed from the New Jersey Experiment Stations.

Infectious laryngotracheitis, F. R. BEAUDETTE (*Poultry Sci.*, 16 (1937), No. 2, pp. 103–105).—A practical review of the status of knowledge of infectious laryngotracheitis, contributed from the New Jersey Experiment Stations.

Observations and experiments with neurolymphomatosis and the leukotic diseases, C. S. GIBBS (*Massachusetts Sta. Bull.* 337 (1936), pp. 31, figs. 6).—In reporting upon an investigation of the methods of transmission of neurolymphomatosis through the egg and of leukotic diseases by means of viruses, erythroleucosis, myeloleucosis, monoleucosis, and lympholeucosis are first dealt with (pp. 2–9). It appears that erythroleucosis and myeloleucosis are filtrable virus diseases, the filtrable agents being contained in the blood stream independent of the cellular elements. "Chickens under a year old are more susceptible than older birds. Predisposing factors appear to be mites [the chicken mite], warm weather, and overcrowding.

"An outbreak of monoleucosis is reported as distinct from erythroleucosis and myeloleucosis.

"Lympholeucosis is due to a histogenous cell identified by the vesicular arrangement of the chromatin of the nucleus. It is usually found infiltrating the tissues of the liver and spleen, and free in the portal blood of affected chickens. The living lympholeucotic cell is resistant to vital strains such as trypan blue, but the dead cell readily absorbs trypan blue. Lympholeucosis was transmitted from diseased to healthy chickens by inoculating portal blood containing large numbers of the living cells directly into the blood stream or the abdominal cavity.

"Neurolymphomatosis, or avian paralysis, is due to a histogenous cell indistinguishable from that occurring in lympholeucosis, except that it has a special predilection for the nervous system, and, under conditions not very well understood, it may invade other adjacent tissues. Chickens inoculated in the nervous system with living cells developed neurolymphomas distally to the point of inoculation in the nerves of the limbs.

"The evidence indicates that the neurolymphomatous cell was transmitted from the hen and possibly from the rooster to the chicken through the egg. The exact method by which the egg is affected was not determined, although neurolymphomatous cells were found infiltrating ovules in affected hens, and cells indistinguishable from them were found in the semen of affected roosters and the follicular fluid of diseased hens. The ovaries and testes of active transmitters were found at necropsy to be infiltrated with neurolymphomatous cells, and no hen or rooster was incriminated in this study as a transmitter that did not show such infiltration of the reproductive organs at some time.

"Symptoms appeared in affected chickens in from 2 weeks to 10 mo. The average period for the 66 birds in this study was 188.85 days, or about 6 mo.

"During the course of these observations and experiments, evidence was secured which indicates that hereditary factors involving resistant and susceptible birds were found in certain forms of neurolymphomatosis, particularly in the infiltration of the ovules of the ovary and the nerve of the eye.

"In conclusion it should be pointed out that the experiments reported in this bulletin were directed toward a study of those forms of neurolymphomatosis which affect the ovary and testes, and of the methods whereby the disease is transmitted through the egg. Transmission through the egg, however, may not be the only way or even the most important way in which the disease is spread."

Salmonella infections in chickens, H. VAN ROEKEL and K. L. BULLIS (Jour. Amer. Vet. Med. Assoc., 91 (1937), No. 1, pp. 48-58).—In this contribution from the Massachusetts Experiment Station, which relates particularly to *S. pullorum* infections and is based upon work previously noted (El. S. R., 76, p. 107), data are presented which show that pullorum disease, fowl typhoid, and possibly other *Salmonella* infections can be eradicated from flocks.

An examination of sixty-four strains of Salmonella sp. isolated from poultry in New South Wales, L. HARR (Austral. Vet. Jour., 12 (1936), No. 6, pp. 233-235).—All recoveries during the past 3 yr. from poultry in New South Wales were found to conform to the reaction of *S. pullorum*. Since the strains came from the main poultry-raising districts of the State there is no reason to suspect that *S. gallinarum* infection occurs in New South Wales.

Toxins of Salmonella aertrycke, R. C. HEETER and L. F. RETTGER (Jour. Immunol., 32 (1937), No. 5, pp. 357-374).—The authors have found that the virulent strains of *S. aertrycke* isolated during recent paratyphoid epizootics in turkeys, as reported upon by Rettger and his associates (El. S. R., 71, p. 232), in which the mortality was as high as 65 percent, did not produce a demonstrable specific toxin in vitro for the natural host. Filtrates of 12-day broth cultures of this organism were not toxic for chickens and turkeys but were highly toxic for mice and rabbits. "These substances are 'nonspecific' in nature, since similar results in mice and rabbits are produced by filtrates of *E[scherichia] coli*. The production of this so-called nonspecific toxin is apparently correlated with cell death. The substances extracted from young cells by alternate freezing, thawing, and subsequent grinding are highly toxic for young turkeys. Substances extracted from *S. pullorum* in a similar manner are highly toxic for chicks. These toxic substances are not specific, since extracts of *E. coli* prepared in the same manner gave similar results. These substances are not true toxins, since no specific neutralizing antibodies were produced against them. The substances isolated by chemical fractionation possess both toxic and immunizing properties for young chicks and must be regarded as true toxins."

Large-scale testing of fowl's blood for the presence of S. pullorum infection, H. P. HAMILTON (Vet. Jour., 93 (1937), No. 5, pp. 175-178).—An account is given of the methods employed in the large-scale testing of blood samples for *Salmonella pullorum* infection, based upon material received from some 15,000 different farms during the past 7 yr. #

Some notes on the efficiency of home-made sodium hypochlorite as a disinfectant, H. P. HAMILTON (Vet. Jour., 93 (1937), No. 4, pp. 153-157).—Reporting upon the efficiency of home-made sodium hypochlorite as a disinfectant, it is pointed out that an available chlorine content of 0.6 percent will kill the highly resistant *Salmonella pullorum* after an exposure of 5 min. at a dilution of 1 part of disinfectant to 10 parts of water.

Tables are given which show the germicidal properties of dilutions of the disinfectant in broth cultures of *S. pullorum* of from 1:2 to 1:20, the concentration of disinfectant necessary to inhibit growth of this organism in optimum conditions of temperature and media, the concentration necessary to inhibit *S. pullorum* and other bacterial growth in drinking water, and a comparison of nonstabilized and stabilized fluid.

Pullorum disease in ducklings, W. R. HINSHAW and H. A. HOFFMAN (*Poultry Sci.*, 16 (1937), No. 3, pp. 189-193).—An outbreak of pullorum disease in 4-week-old chicks and 1-week-old mallard ducklings in a flock in California is reported upon, circumstantial evidence being presented that the disease was transmitted to the ducklings from the chicks. "Complete studies of the strains of *Salmonella pullorum* isolated from the ducklings and chicks are included in the report. These strains differed from the laboratory strains with which they were compared in the production of a wrinkled growth on agar, the formation of a slight pellicle on meat extract broth, and in their failure, when first isolated, to produce acid and gas in arabinose medium. After 1 yr. the duckling strain began producing acid and gas in arabinose broth. Reciprocal agglutination-absorption tests made with two tested laboratory strains as controls showed the strains to be antigenically identical to *S. pullorum*. Both the duckling and chick strains produced typical pullorum disease in chicks but failed to infect one lot of 2-day-old Muscovy and one lot of 11-day-old mallard-Peking cross-bred ducklings."

Relative abundance of crop worms in turkeys: Macroscopic differentiation of species, E. E. WEHR (*Vet. Med.*, 32 (1937), No. 5, pp. 230-233, figs. 3).—In an examination made of a large number of turkey esophagi collected at one of the poultry markets in Washington, D. C., *Capillaria contorta*, *C. annulata*, and *Gongylonema* sp. (probably *G. ingluvicola*), named in the order of their relative abundance, were found to be the parasites of the esophageal mucosa of turkeys in that vicinity.

An outbreak of parasitic necrosis in turkeys caused by *Plagiorchis loricola* (Skrjabin), A. FOGGIE (*Jour. Helminthol.*, 15 (1937), No. 1, pp. 35, 36, fig. 1).—A brief account is given, together with a description, of a small fluke (*P. loricola*) which was found to have caused the death of 11 in a flock of 23 turkey poults at the time of visitation of a farm in Northern Ireland.

Parasitic tumors in wild birds, L. C. MORLEY and J. E. SHILLINGER (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 1, pp. 94-97, figs. 2).—An account is given of an extensive tumorous growth covering the breast of a red-winged blackbird, collected in New York State which appears to have been due to the mite *Harpyrynchus brevis* (Ewing).

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Nebraska Station] (*Nebraska Sta. Rpt.* [1936], pp. 6, 7).—The progress results are briefly presented of investigations of heating water for livestock, insulated electric brooders in uninsulated poultry houses, performance of rubber tires on tractors, and bindweed eradication machinery.

[Agricultural engineering investigations by the Ohio Station], G. W. McCUEN, C. O. REED, R. C. MILLER, V. L. OVERHOLT, I. P. BLAUSSER, G. H. STRINGFIELD, E. A. SILVER, and C. W. ELLENWOOD (*Ohio Sta. Bul.* 579 (1937), pp. 108-112, 115-117, figs. 4).—The progress results are briefly presented of investigations on farm operating efficiency, the use of electricity for soil sterilization and heating for tomato improvement, mechanical equipment for the planting

of irregularly shaped kernels of hybrid corn, pressure and load exerted by ear corn in cribs, apple washers to remove spray residue, and the combine harvester-thresher.

Headwaters control and use (*U. S. Dept. Agr., Soil Conserv. Serv. and Forest Serv., 1937, pp. IX+[1]+261, pls. 2, figs. 71*).—This publication contains the papers presented at the Upstream Engineering Conference held in Washington, D. C., September 22 and 23, 1936 (*E. S. R., 75, p. 577*). It has been published in cooperation with the U. S. Rural Electrification Administration. It contains papers (and discussions) on Basic Principles of Water Behavior, by T. Saville (pp. 1-15); Surface Run-Off Control, by R. E. Horton (pp. 16-49); Giving Areal Significance to Hydrologic Research on Small Areas, by M. Bernard (pp. 50-75); Influence of Vegetation on Land-Water Relationships, by I. Bowman (pp. 76-105); Management and Use of Forest and Range Lands, by E. H. Clapp (pp. 109-119); Management and Use of Agricultural Lands, Including Farm Woods and Pastures, by H. H. Bennett (pp. 120-157); Control and Use of Small Streams, by G. D. Clyde (pp. 158-175); A Survey of Effectiveness of Dams of the Soil Conservation Service (pp. 179-181); Farm Ponds for Water Supply and Flood Control, by W. H. McPheters (p. 181); Highway Construction and Water Conservation, by R. D. Brown (pp. 181, 182); Malaria Control, by L. L. Williams, Jr. (pp. 183, 184); Spreading Water Over Absorptive Areas for Storage Underground, by A. T. Mitchelson (pp. 184-187); Artificial Methods of Ground-Water Recharge, by R. Nebolsine (pp. 187, 188); Ground Water for Drought Relief, by J. Jacobs (p. 188); Zoning as a Technique for Water Conservation, by G. H. Gray (p. 188); Upstream Engineering and the Conservation of Wildlife Resources (p. 189-192); Relationships of Animal Life to Land and Water Resources, by C. L. Forsling (pp. 193-195); Wildlife—A Land Crop Favorable to Conservation of Water and Soil (pp. 195-197); Influence of Animal Life on Soil and Water Conservation, by E. G. Holt (pp. 197, 198); Physical and Functional Relationships, by M. L. Cooke (pp. 201-209); The Comprehensive Engineering Point of View, by S. M. Woodward (pp. 210-222); Big Waters and Little Waters, by E. M. Markham (pp. 223-226); Control and Use of Little Waters in France, by M. A. Magnein (pp. 227-232); Building Toward a Permanent Agriculture, by J. G. Lipman (pp. 233-236); On Behalf of a Continent, by M. Maverick (pp. 237-245); and The Human Value in Upstream Engineering, by C. H. Whitaker (pp. 246-249).

Soil and water conservation investigations, G. W. MUSGRAVE and R. A. NORRIS (*U. S. Dept. Agr., Tech. Bul. 558 (1937), pp. 182, figs. 59*).—This is a progress report of investigations in the Missouri Valley loess region at Clarinda, Iowa, during 1931-35, conducted cooperatively by the Soil Conservation Service and the Iowa Experiment Station.

Preliminary data on canopy interception indicate the marked effects which various types of vegetation may have in the protection of the land surface, including a considerable portion of the control of erosion and run-off which is so commonly noted for alfalfa, clover, bluegrass, and even small grain and corn when the latter are fully developed.

Marshall silt loam was found to have an infiltration rate from 7 to 10 times that of Shelby silt loam. Soil porosity is indicated as perhaps the most important single factor, with the soil moisture content and the vegetative cover of less importance. Soil moisture apparently reduces infiltration on these two soils approximately in proportion to the space volume which it occupies. Vegetative cover may increase total infiltration through its effect in reducing the rate of run-off. It is doubtful whether any increase in rate of infiltration may be attributed to root effects of growing plants. Insofar as vegetative cover

prevents the application of turbid water to the soil profile, normal infiltration is maintained thereby as shown by other investigators.

The increase in soil porosity resulting from the application of organic matter to the surface of a normal profile has significantly (1) increased percolate through 3-ft. profiles of both permeable and relatively impermeable soils by large proportions, (2) decreased run-off, and (3) increased the store of potentially available water. The treatments have reduced erosion by large amounts, but have not exerted any marked effects upon evaporation. The potentially available water (rainfall less run-off) has been increased by about 2 surface inches a year in the Marshall and by about 1½ surface inches a year in the Shelby soil series by these treatments.

As the land slope is increased, impounding is decreased so rapidly that a treatment which will impound 2½ in. on level land will impound less than one-fourth as much on a 15-percent slope.

The control of run-off is the product of a large number of factors. The average run-off from manured corn has been reduced to 10 percent of the total effective precipitation, from bluegrass to 6 percent, alfalfa 6, clover 2, and from contour-listed corn to a mere trace. From manured land in corn, the maximum percentage of run-off from any rain has been 43 percent, from contoured listed corn 19, from bluegrass 14, from clover 6, and from alfalfa 5 percent.

The amount of soil carried by a cubic foot of run-off from bluegrass has averaged 0.19 lb., from continuous alfalfa 0.19, and from rotation clover 0.10 lb. of soil per cubic foot. These figures may be contrasted with a density of more than 5 lb. per cubic foot from continuous corn on eroded soil, continuous corn with rows in the direction of slope, and from fallow land, whether treated or untreated.

The effect of adding organic matter to Marshall silt loam which was excessively eroded was to reduce greatly run-off and erosion and to increase markedly soil moisture, rate of growth, and yield of corn. Green manure in the form of sweetclover produced yields above 50 bu. of corn per acre 2 yr. after artificially eroding the profile to a depth of 12 in.

Strip cropping is shown to be a somewhat different practice on the permeable Marshall silt loam than on less permeable soils. Combining primarily the effects of surface impounding and infiltration, theoretical protection equivalent to the maximum rain of a 15- to 20-yr. frequency may be secured through minor modifications of present farm practices. Additional protection may be provided by winter cover crops and the incorporation of organic matter in the soil in economical and practical ways. The study of slope lengths has revealed the uncertainty lying in an attempted estimate of the optimum width of crop strip.

Detailed studies of the costs of construction of about 10 miles of terraces revealed that on three sizes of terracing outfits, covering the range of tractor power which might be available, respectively, to the operator of an ordinary-sized Corn Belt farm, an extra large farm, and a group of farms or a small contractor engaged in earth-moving operations, there was very little difference in cost per unit length of terrace constructed between a 10- and a 15-hp. wheel-type tractor. A 15-hp. track-laying-type tractor built terraces for less than 60 percent as much per unit of length as either of the wheel-type tractors. The depreciation and interest on the investments were not considered in any of these computations.

Experienced grader and tractor operators may be able to reduce the cost of terrace construction to approximately 70 percent of that entailed by inexperienced operators. With soil in good condition for handling by the grader

it may be possible to build terraces with only 65 percent as much cost as will be required when the soil is hard and dry. Occurrence of gullies may increase the cost of terracing by as much as 20 to 25 percent in the Marshall silt loam area. The cost of building a terrace from 100 to 150 ft. long is nearly twice as great per unit of length as for a terrace 1,600 ft. long. This is due to the great amount of lost time in turning at the ends of the terrace.

Suspended-net woven-wire dams have not proved very satisfactory in gullies in which small amounts of water flow continuously. The Nebraska-type brush dam with suitable backing of woven wire on the upstream side seems quite satisfactory for ordinary types of gully control. For sidehill gullies, probably the most satisfactory control is terracing near the tops of the hills in order to prevent cutting at the head of the gully, then diverting water out of gullies which have already started and fencing them to keep out livestock.

Terrace-outlet ditches have been controlled quite satisfactorily by stake and rock checks reinforced by sod strips both above and below each check. Plank checks with sod strips above and below have thus far shown fair success.

In studies of the operation of farm machinery over terraced areas, a 10-ft. corrugated roller was found to operate quite satisfactorily parallel to the terraces. A 14-ft. disk harrow of standard construction seemed to lack somewhat in flexibility and clearance. A 16-7 fertilizer grain drill was found to be too lightly constructed to stand the strain due to operation on uneven ground either parallel to or across terraces. A 20-ft. flexible spike-tooth harrow of the pipe-bar type with a specially designed harrow cart has been found to operate very satisfactorily either parallel to or across terraces, but more especially when used up and down the hills at nearly right angles to the terraces. An 8-ft. power-driven grain binder was operated on terraced land with only partial success, mostly because of lack of clearance and flexibility for operation over uneven ground. Three-row corn-planting equipment functioned fairly well, but difficulty was encountered with the three-row cultivating equipment mounted on the same tractor. On terraces with vertical spacings of 4, 5, and 6 ft., a long variable graded terrace with intermediate spacing lost the greatest amounts of soil and water per unit of area and the one with the narrowest spacing lost more than the one with the widest spacing. When the terraces were uniformly graded the terrace with the widest vertical spacing lost more soil and water per unit of area than either of two others. In general, the flatter the grade of long variable graded terraces or long uniform graded terraces with the same vertical spacings the smaller the losses in soil and water.

There is a slight tendency for short terraces to lose more soil and water per unit of area than is the case with long terraces. Level terraces with open ends have operated very satisfactorily so long as they were kept on a good quality of Marshall soil. Level terraces with closed ends have so far not proved satisfactory.

A terrace planted to continuous corn shows greater losses of soil and water than those planted to either first- or second-year corn, oats, or clover. No very significant differences have been noted between any of the other four crops when compared among themselves.

An appendix includes additional tabular data on precipitation and run-off as related to erosion.

The homemade centrifugal pump, O. W. MONSON and H. E. MURDOCK (*Montana Sta. Cir. 150 (1937), pp. 20, figs. 8*).—This circular replaces Bulletin 324 (E. S. R., 76, p. 400), which describes the home-made centrifugal or box pump which has been developed by the station. This pump is capable of delivering a volume of water sufficient for irrigation when operated under a low lift. Tests

showed that it will be practical as an irrigation pump for lifts of less than 12 ft., particularly if the pumping season is short and investment in high-priced commercial equipment is not justified.

The pump consists of a well or discharge box built from matched lumber, the height of which is equal to the operating lift plus about 3 ft. for submergence. At one side of the discharge box is an impeller chamber housing a double impeller mounted on a shaft supported on a thrust bearing. The impeller is driven by means of the pulley at the upper end of the shaft.

The water enters the impeller chamber through two intake holes around the impeller shaft, one at the top and the other at the bottom. As the water enters the impeller it is thrown outward by the centrifugal force of the rotating impeller and collects in a spiral around the outside of the impeller and is guided or conveyed into the discharge box.

Tests on use of rubber tires and steel wheels on a farm tractor, H. E. MURDOCK (*Montana Sta. Bul.* 339 (1937), pp. 35, figs. 32).—A large number of tests on a standard tractor are reported. All tests were run on summer-fallowed ground, part of which had been plowed and the remainder fallowed with a one-way disk, but all in approximately the same condition. The season was unusually dry, so the soil was very loose and dusty for most of the test period.

In fuel consumption the differences were small for the various series of tests with rubber tires but decreased slightly with an increase of wheel weights. The fuel consumption with heavy loads decreased slightly when inflation pressure was decreased. The fuel consumption was less with rubber tires than with steel wheels by from one-sixth to two-fifths of a gallon per hour, or about 5 to 8 percent less for the rubber tires. There was some variation with the load.

An increase in the drawbar pull decreased the speed, this decrease being more rapid with the lower wheel weights. The maximum drawbar pull and horsepower were higher with the large rubber tires. The maximum drawbar pull varied slightly with the inflation pressure, being lower for the high inflation pressures, but the maximum practicable drawbar pull was about the same in all gears with rubber tires. The maximum horsepower with rubber tires was greater in the higher gears. The addition of wheel weights with the rubber tires increased both the maximum drawbar pull and the horsepower. The pull was increased an amount varying from one-third to two-thirds the value of the added weight and averaged nearly one-half the added weight. The increase in the maximum horsepower caused by adding 870 lb. amounted to from 25 to 65 percent.

With steel wheels the maximum drawbar pull was greater for the lower gears, but the maximum horsepower was about the same for all gears. The maximum drawbar pull and horsepower with the large rubber tires were higher than for the steel wheels, while for the small tires they were less, but the differences were not great.

The slip with rubber tires was generally higher than that with the steel wheels and lugs, except at the lower inflation pressures and with the higher amount of wheel weights. The slip with the rubber tires was greater with the higher inflation pressures and less with a larger wheel weight. The rate at which the slip increased with an increase in the drawbar pull was less with the large rubber tires than with the small tires.

In high gear the tractor pulled larger loads when equipped with rubber tires than with steel wheels. Acre costs of operations with rubber tires were less in the high gears, while with steel wheels they were more uniform in the three gears.

Rotary spray irrigation, O. E. ROBEY (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 212-217, figs. 5).—Information is given on the mechanical details of equipment used for rotary spray irrigation.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Ohio Station, 1933-36] (*Ohio Sta. Bul.* 579 (1937), pp. 100-106).—Results of studies not previously noted are reported as follows: (1) Table, by F. L. Morison, showing the productivity balance, manure equivalent, percentages of rotated areas in row crops, small grains, and hay and rotation pasture, the productivity factor for hay, and yields per acre of corn and wheat on 422 farms in 6 counties in 1936, grouped into 4 groups on the basis of soil depletion; (2) table, by C. W. Hauck, showing customers' methods of selecting canned foods in a Columbus retail grocery store before and after 3 months' advertising, featuring grade labeling; (3) table, by G. F. Henning, showing the factors influencing farmers in 5 areas of the State to market live-stock through cooperative or noncooperative agencies; and (4) table, by R. W. Sherman, showing the average amounts charged by distributors and received by producers per 100 lb. of milk sold as fluid milk and cream during the first 3 mo. of 1933 and 1934, September 1934, February 1935, and August 1936 in 10 markets of the State, representing approximately 55 percent of the milk-consuming population of the State.

[Papers on agricultural economics] (*Pacific Coast Econ. Assoc., Ann. Conf., Papers and Proc.*, 14 (1935), pp. 1-7, 55-74).—Included are the following papers on farm economics presented at the fourteenth annual conference of the Pacific Coast Economic Association, December 1935: The New Relation of Government to Agriculture in the United States, by W. L. Wanlass (pp. 1-7); Changes of Emphasis in Government Efforts to Aid Agriculture, by E. F. Dummer (pp. 55-61), with discussion by H. C. Farnsworth (pp. 62, 63); Economics of Production Control, by E. L. Potter (pp. 64-67), with discussion by C. Akerman (p. 68); and Governmental Control of Agricultural Prices, by G. E. Hoover (pp. 69-72), with discussion by N. J. Silberling (pp. 73, 74).

[Papers presented before the British Agricultural Economics Society] (*Jour. Proc. Agr. Econ. Soc.*, 4 (1935), No. 1, pp. 14-83, figs. 2; 4 (1936), Nos. 2, pp. 89-149, figs. 2; 3, pp. 167-258, figs. 5).—These reports continue the series previously noted (*E. S. R.*, 72, p. 266). The following papers, with discussions, presented at the conferences in 1935 and 1936 are included: No. 1, Conference at Cambridge, June 28-July 1, 1935—Presidential Address—The Expectation of Agricultural Recovery, by R. R. Enfield (pp. 14-43); Agriculture in France, by M. Augé-Laribé (pp. 44-54); Scientific Progress and Agricultural Employment, by A. Bridges (pp. 55-76); and The Scottish Crofter, by J. M. Ramsay (pp. 77-83); No. 2, Conference at London, December 10-11, 1935—Food Supplies and Consumption at Different Income Levels, by E. M. H. Lloyd (pp. 89-120); Statistical Investigations Into Organised Marketing of Milk, by J. L. Davies (pp. 121-134); and Land Settlement and Unemployment, by A. W. Menzies-Kitchin (pp. 135-149); and No. 3, Conference at Oxford, July 3-6, 1936—Presidential Address—The Relations of Land Tenure and Agriculture, by H. M. Conacher (pp. 167-202); World Agriculture and the Problems of Nutrition, by F. L. McDougall (pp. 203-222); Research and Price Control, by R. L. Cohen (pp. 223-240); and Organising Farm Workers, by J. F. Duncan (pp. 250-258).

[Farm economics in Great Britain] (*Farm Econ. [Oxford Univ.]*, 2 (1936), Nos. 1, pp. 20, figs. 2; 2, pp. 21-36, figs. 5; 3, pp. 37-52, figs. 2; 4, pp. 53-72, figs. 3).—These publications continue the series previously noted (*E. S. R.*, 71, p. 264) and include in addition to lists of publications and charts showing prices of agricultural commodities in England and Wales the following articles: The Outlook for Milk, by C. S. Orwin (pp. 1, 2); The Condition of Cowsheds, by R. N. Dixey (pp. 3, 4); Some Trends in Dairy Farming in South Devon, by W. H. Long (pp. 5-8); Changes in Milk Output on Ten West Country Grassland Dairy Farms, by F. H. Villiers (pp. 9, 10); Observations on the Depreciation of Cows and

Calving Records of a Commercial Farm, by F. R. G. N. Sherrard (pp. 11-13); Why Not Separated Milk? by S. M. Makings (pp. 14, 15); Fruit Consumption—The Importance of Imports, by J. F. Cahan (pp. 15-17); Food Imports and the Italian Sanctions, by C. S. Orwin (pp. 21, 22); Sugar Beet Costs and Returns, 1932-35, by A. Bridges (pp. 22-24); Pig Production Costs in Denmark, by A. W. Menzies-Kitchin (pp. 25-27); Milk: Delivery to the Station, by R. N. Dixey (pp. 27, 28); Seasonal Variation in the Output and Prices of Eggs, by O. J. Bellby (pp. 29-32); Tenancy Changes on Small Holdings, by W. F. Darke (p. 37); Winter Food Requirements for Milk Production, by C. V. Dawe and J. E. Blundell (pp. 38, 39); Monthly Cash Receipts and Expenses on 18 Yorkshire Poultry Farms, by J. D. Nutt (pp. 40, 41); Giving the Consumer the Manufacturing Milk, by S. M. Makings (pp. 41-44); The Trend of Milk Prices in the Eastern Counties, by P. E. Graves (pp. 44-46); Change in Market Receipts of Fat Cattle Since the Introduction of the Subsidy, by R. P. Askew (pp. 46-48); Combine-Harvesting Costs in 1935, by R. P. Askew (pp. 53-57); Machine Versus Hand-Milking, by A. L. Jolly (pp. 57-59); The Relationship Between the Prices and Costs of Pork and Bacon Pigs, by J. R. Lee (pp. 59, 60); Causes of the Recent Rise in Egg Prices, by O. J. Bellby (pp. 61-63); The Effect of Recent Currency Depreciation on British Agriculture, by R. Cohen (pp. 63-67); and Milk in Schools, by K. A. H. Murray (pp. 67, 68).

Foreign Agriculture, [June 1937] (U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr., 1 (1937), No. 6, pp. 261-314, figs. 3).—Included are articles, An Appraisal of Recent French Wheat Policy, by L. D. Mallory (pp. 203-298), and The London Sugar Agreement, by E. P. Keeler (pp. 299-310), and notes on the promotion of cotton production in southeastern Europe (pp. 311, 312), British government plans additional aids to farmers (pp. 312, 313), and Japan-India cotton agreement extended (pp. 313, 314).

Hogs in Belgian agriculture, H. E. REED (U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr. Serv., F. S. 68 (1937), pp. [2]+[12]).—The number of hogs, types, breeds, management and feeding practices, marketing, slaughter, and processing in Belgium are briefly described. Consumption of pork, imports into, fat deficiency in, and trade relations with other countries are discussed. The conclusion is reached that conditions do not appear favorable for future outlets for American pork products in Belgium.

International yearbook of agricultural legislation, 1933 [trans. title] (Inst. Internat. Agr. [Roma], Ann. Internat. Lég. Agr., 23 (1933), pp. LXX+1259).—This volume continues the series previously noted (E. S. R., 72, p. 270). The legislation regarding agricultural and commercial statistics, trade in agricultural products, prices, tariffs and taxes, diseases of and regulations pertaining to plants and animals, agricultural education, cooperation, insurance, credit, rural property, emigration and migration, rural hygiene, etc., is included. The introduction summarizes and discusses the legislation.

Possible savings through changes in local government, H. C. BRADSHAW and L. P. GABBARD (Texas Sta. Bul. 540 (1937), pp. 92 figs. 4).—This study is based upon data regarding receipts and expenditures in 1933 for 38 counties and the 1,130 school districts therein. In selecting the counties the State was divided into 8 areas based principally on the type of farming. In each area counties were selected representing low, average, and high land areas, populations, and assessed valuations. Information was also obtained as to number and qualifications of employees, budgeting, purchasing, custody of funds, maintenance of roads, protection to person and property, and other governmental activities.

The duties, qualifications, and compensation of county officers in Texas are described. Tables are included and discussed showing the receipts in 1933 of

the counties and school districts by sources and the expenditures classified according to character and functions. County expenditures are also classified according to object. The possibilities of savings in expenditures of the counties and school districts are discussed and recommendations made as to methods by which such savings may be effected.

The average total per capita costs in the 38 counties was \$18.83, of which \$3.16 was for education. The trend was for costs to decrease with population, the average for the 4 counties with from 2,197 to 5,000 population being \$28.18 and \$12.36, respectively, as compared with \$15.99 and \$7.58, respectively, for the 6 counties with over 35,001 population.

The recommendations for the school districts include (1) the putting into effect of the reorganization plan of the State Board of Education, (2) the apportionment of State funds to equalize and improve educational advantages, and (3) appointment of the State and county superintendent of schools on the basis of merit and to hold as long as services are satisfactory.

The recommendations as to counties include (1) consolidation of counties, (2) the adoption of either a county manager or county executive plan of organization, (3) development of cooperation among counties in handling certain functions, and (4) additional State interest in and responsibility for the work performed by the counties. In county consolidation it is recommended that a county should have a minimum population of 20,000 and a minimum assessed valuation of from \$10,000,000 to \$12,000,000. Consolidation of counties of less than 5,000 population, it is estimated, would save \$2.91 per capita, being 21 percent of the total cost of county government, 25 percent of the current or operating costs, and 63 percent of the costs affected by consolidation.

Farm tenancy in the United States, 1918-1936—A selected list of references, compiled by L. O. BERCAW (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 70 (1937), pp. VIII-302).—This bibliography is a revision of that previously noted (*E. S. R.*, 74, p. 557). It includes 1,070 selected references to books, pamphlets, and periodical articles on farm tenancy and farm leases in the United States. There are a few references to publications issued prior to 1918 and in 1937, and a few on corporation farming and group management of farms. The bibliography is divided into three main sections—general references, references by geographical divisions, and references by States. Author and subject indexes are appended.

Recent agricultural credit developments relating to commercial banks. N. J. WALL (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1937, pp. [2]+16, figs. 2).—This report is based on data for the year ended June 30, 1936, secured in cooperation with the Federal Deposit Insurance Corporation, the Comptroller of the Currency, and the Board of Governors of the Federal Reserve System. It continues the study previously noted (*E. S. R.*, 76, p. 121). A table is included showing the outstanding short-term credit of Federally sponsored agencies, December 31, 1929-35, and June 30, 1936.

Agricultural loans of commercial banks decreased approximately 12 percent from December 31, 1934, to June 30, 1936, there being a decrease of \$146,007,000 in personal and collateral loans and a decrease of \$9,525,000 in loans secured by real estate. The latter, however, increased slightly from December 31, 1935, to June 30, 1936. The decrease in personal and collateral loans was due largely to reductions of outstanding loans secured by warehouse receipts, bills of lading, etc. The States where such loans had been secured largely by livestock showed a slight increase. Short-term loans (excluding emergency drought, rehabilitation, and seed loans) of Federally sponsored institutions also showed a slight declining trend. Deposits in country banks showed a very marked rise since the spring of 1933, demand deposits in Federal Reserve member banks in places of less than

15,000 population in 20 leading agricultural States being 105.8 percent of the 1923-25 monthly average as compared with 43.2 percent in April 1933. The increase was due to increased farm prices and income and disbursements for work relief, drought expenditures, and other emergency programs.

Farm mortgage foreclosures in South Dakota, 1933-34-35-36, G. LUNDY (*South Dakota Sta. Circ. 17, Sup. [1937], pp. [6] figs. 3*).—This supplements the circular previously noted (E. S. R., 71, p. 867).

A graphic summary of physical features and land utilization in the United States, O. E. BAKER (*U. S. Dept. Agr., Misc. Pub. 260 (1937), pp. 11+57, figs. 70*).—This is one of a projected series previously described (E. S. R., 77, p. 117), dealing with temperature and duration of the frost-free season, moisture, topography, and soils.

Land use and soil conservation practices in Mecosta County, E. B. HILL and H. B. TAYLOR (*Michigan Sta. Quart. Bul., 19 (1937), No. 4, pp. 207-212*).—The data obtained in a farm management survey in 1936 of 78 farms in two townships are analyzed to show the land uses, crop yields, number of livestock, operator's age and experience, farm indebtedness and financial returns, and the butterfat production and returns per \$1 worth of feed fed in the dairy enterprise. The soil conservation practices in use are briefly discussed.

On farms with less than 40 percent of the rotation land in hay and pasture, crop yields, particularly corn, wheat, oats, and potatoes, averaged about 10 percent lower than in the over 40 percent group. The amounts of livestock per farm, size of dairy herds, and pounds of butterfat sold per cow were about the same in both groups. The farmers in the over 40 percent group fed their cows 22 percent more hay, 12 percent more concentrates, and 18 percent less succulent roughages and dry roughages other than hay. The average amount left for operator's labor and management wage (net returns less allowance for unpaid family labor and interest on investment) on 77 of the 78 farms was \$410. Chiefly because of lower cash expenses, it was \$446 on the 36 farms in the less than 40 percent group and \$378 on the 41 farms in the over 40 percent group.

Thirty-one of the farmers had changed their cropping system since 1930 by increasing the acreages in legume hay 19 percent and corn 1 percent and by decreasing those in nonlegume hay 42 percent, wheat 7 percent, and other small grains, potatoes, and rotation pasture each 4 percent. On the 78 farms there were increases from 1930 of 6 percent in cows and 57 percent in sheep and decreases of 4 percent in hens and 13 percent in hogs. About 15 percent of the farmers were considering increasing the size of their farms; 9 percent were considering decreasing.

A program for land use in northern Minnesota: A type study in land utilization, O. B. JESNESS, R. I. NOWELL, ET AL. ([*Minneapolis*]: Univ. Minn. Press, 1935, pp. XVI+338, pls. 41, figs. [40]).—This type study in land utilization was made by the University of Minnesota and the U. S. D. A. Bureau of Agricultural Economics. The volume includes chapters by O. B. Jesness on the background of the study, present policies and programs of adjustment, and translating proposals into effective programs; by R. I. Nowell on the natural, social, economic, and governmental characteristics of the region, present uses of land, land classification and zoning, acquisition and utilization of land for public purposes, and problems involved in moving farm families; by H. F. Hollands on the economic and social consequences of planless land use; by J. H. Allison on improved utilization of private forest lands; by G. A. Pond and C. W. Crickman on improved use of agricultural land; and by M. Regan on adjustments in local government.

Factors affecting the economic self-sufficiency of the Middle Rio Grande Conservancy District, P. W. COCKERILL (*New Mexico Sta. Bul.* 247 (1937), pp. 20).—"The purpose of this bulletin is to set forth suggestions for improvement in marketing food products produced for the home market, together with the consideration of some of the factors entering into the selection of enterprises for the purpose of production for both local and outside markets." The possibilities of producing products for which a national market exists are briefly discussed. The bulletin, however, is devoted chiefly to a discussion of the production of fruits, vegetables, eggs, dairy products, etc., for local consumption in competition with shipped-in products. This discussion is based on data obtained from 450 housewives and 50 leading grocers in Albuquerque, and 18 merchants in Gallup, Bernalillo, Santa Fe, and Las Vegas, N. Mex.

Recommendations for the improvement of agricultural conditions in Kansas (*Topeka: Kans. State Planning Bd., 1936. pp. [47], [fig. 1]*).—This report of the Kansas State Planning Board to the National Resources Committee includes its recommendations as to the coordination of land use and water problem studies, administrative policies, land use, taxation and credit policies, research, demonstration, surveys and investigations, and water use. Appendixes include memorandums on research, prepared by the Kansas Experiment Station and the division of extension of the Kansas State College, an article on Character and Composition of the Population of Kansas, by C. D. Clark, and a chart and table showing the extent of past Federal assistance to agriculture in the State.

Large scale and corporation farming: A selected list of references, compiled by E. M. COLVIN (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 65 (1937), pp. VII+121).—This selected list of 406 references covers the period December 1929–April 1937, with a few references to earlier material. It supplements a bibliography previously noted (*E. S. R.*, 63, p. 84) and supersedes that on group and chain farming in the United States (*E. S. R.*, 69, p. 603). The references are arranged by countries, those in the United States being subdivided into the following groups: General, group management, Great Plains and Middle Western States, Southern States, and individual States.

Economic analysis of potato production in northern Indiana, L. ROBERTSON (*Indiana Sta. Bul.* 412 (1936), pp. 28, figs. 17).—The adaptability of the 22 northern counties of Indiana for potato production, the production and trends in production in these counties, and the market outlets for potatoes from the section are discussed. Data for 1934 as to costs of production and receipts from potatoes obtained from 56 farms with late muck potatoes, 18 with late upland potatoes, 15 with early muck potatoes, and 15 with early upland potatoes are analyzed. The factors affecting costs, the labor distribution on potatoes, and ways of improving the market for northern Indiana potatoes are discussed.

Sugar beet production and marketing costs, [1936], K. T. WRIGHT (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 4, pp. 217–222).—Records from 87 farmers obtained in the fourth year of the study (*E. S. R.*, 75, p. 866) are analyzed to show the yields; production, marketing, and labor costs; machine work done; and the effects of costs of labor, power, and machinery per acre on yields and total production costs, and of distance to sugar beet plant on production and marketing costs.

An economic study of livestock farms in Maryland, W. E. BELL, A. B. HAMILTON, S. H. DEVAULT, and D. MEADE (*Maryland Sta. Bul.* 406 (1936), pp. 253–298, figs. 14).—"The purpose of the study was (1) to determine whether commercial livestock farms in the State are being operated on a profitable

basis, (2) to determine the influence of various factors of production on profitability, (3) to determine livestock management practices, and (4) to determine what combinations of enterprises, factors of production, and management practices give the largest net returns." Data were secured regarding 50 farms in 1934 and 57 farms in 1935 in 5 counties in central Maryland.

The labor incomes in 1924 ranged from \$1,546 to —\$3,617, averaging —\$151, and in 1935 from \$1,331 to —\$2,373, averaging \$94. For the 2 yr. 54 farms had plus labor incomes, averaging \$978, and 53 minus labor incomes, averaging —\$1,038. The profitable farms as compared with the unprofitable farms averaged 49 acres less, 10 acres less in crops, \$10,477 smaller total investment, \$10,405 less investment in land and buildings, 1.3 more animal units, \$859 larger total receipts, \$633 less total expenses, \$478 greater receipts from livestock and \$98 greater receipts from crops, and 9.1 mo. less of hired labor. Yields per acre of corn, silage, wheat, and barley were greater and those of rye, oats, alfalfa, and other hay less on the profitable farms.

The livestock organization management and marketing for the farms are described. Suggestions are made as to how practices may be improved with a view to increasing labor incomes.

Cattle ranching in Montana: An analysis of operating methods, costs, and returns in western, central, and eastern areas of the State, M. H. SAUNDERSON and D. W. CHITTENDEN (*Montana Sta. Bul. 341 (1937), pp. 32, figs. 2*).—"The purpose of this bulletin is (1) to describe the operation and management method of beef cattle ranches, and (2) to analyze operating costs and income as related to operating practices and ranch management from the standpoint of the ranch operator." It is based chiefly on detailed records covering the period 1929-34 on the resources and operations of about 100 ranches varying in size from 100 to 3,000 head of cattle, the most common number being about 400. The ranches included are fairly typical of the different regions of the State—western, central, and eastern or plains. The annual operating costs per head, production costs for different types of cattle, labor costs, land charges, and hay, feed, equipment depreciation, and bull service costs are discussed. The effects on income of percentage calf crop; weight, quality, and breed of animals; death losses; classes of animals marketed and their prices in relation to production costs; size of ranch in relation to efficient management; and family income needs and supplemental enterprises are also discussed. Operating data for three individual ranches are included in an appendix.

Western cattle and sheep areas, described for the use of cooperative marketing and credit associations, L. B. MANN (*Farm Credit Admin. [U. S.], Coop. Div., Circ. C-103 (1936), pp. 1-101, figs. 28*).—The production and marketings are described for each of 71 cattle- and 70 sheep-production, grazing, and feeding areas into which the 17 Western States have been divided, with a view to assisting cooperative marketing and credit associations.

Purchases of feeds and grains in Alabama, 1935: A progress report, B. T. INMAN (*Alabama Sta. Circ. 77 (1937), pp. 11, fig. 1*).—This is a progress report in a study of the balance of production and consumption of farm products in Alabama. Tables are included showing for 1935 the quantities and retail values of State-grown and out-of-State-grown commercial feeds and oats, corn, cottonseed hulls, and different kinds of hay. A map shows by counties the percentages of State feed expenditures in 1929. A table shows the number of farms by type of farm reporting expenditures for feed per farm and the total and average expenditures for the different types of farms.

"Feed dealers sold \$10,295,827 worth of feeds in Alabama in 1935, \$6,409,363 of which were for feeds not grown in the State. The chief shortage of feed

materials in Alabama is in those materials with medium and low protein content, particularly grains. The present production of such high protein feeds as cottonseed meal and peanut meal are in excess of needs with present feeding standards. The shortage of grains for food and feed materials could be modified very much by the increased production of corn and oats. Corn and oats for both the food and feed markets can be supplied in the State if certain improvements are brought about such as: (a) Adequate storage space, (b) weevil control, (c) better standardization of corn varieties, (d) improved quality of corn, and (e) lower production costs."

Cooperative marketing of agricultural products, W. W. FETBOW (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 3 (1936), pp. IV+106, figs. 20*).—The development and present status in the United States of cooperative associations for marketing cotton, fruits, vegetables, nuts, grains, livestock, dairy products, poultry products, tobacco, wool and mohair, rice, dry beans, forage crops, seeds, honey, maple sirup, cane sugar and sirup, and sugar beets are described.

A study of grades, price trends, and sales on the Indianapolis Producers' Market, K. I. FAWCETT and F. C. GAYLORD (*Indiana Sta. Bul. 411 (1936), pp. 44, figs. 32*).—Data were obtained by a man experienced in the grades and quality of fruits and vegetables as to the volumes, grades, sources of supplies, prices received, etc., on the Indianapolis Producers' Market during a 22-week period, from April to September 1933. Tables show the values of dealers' and producers' sales, monthly receipts and value of sales for different products, value of weekly sales, sales from the more important Indiana counties and dealer sales by State of origin, weekly receipts, and average weekly prices of different fruits and vegetables.

The marketing of different products is described with graphs for the more important, showing the weekly variations, receipts, and prices.

Fifty different fruits and vegetables were sold during the period, the total sales being approximately \$553,000. Producers received 62 percent and dealers 38 percent of the total value. Of the total sales, 84 percent were of tomatoes, cantaloups, apples, peaches, potatoes, corn, strawberries, cabbage, green beans, pickles, watermelons, onions (dry), greens, and raspberries. Sales included products from 23 States and 41 Indiana counties, 73 percent of the latter being from 19 counties.

A survey of organization and methods of operation of twenty Indiana city markets, F. C. GAYLORD and K. I. FAWCETT (*Indiana Sta. Bul. 417 (1936), pp. 28, figs. 9*).—This study of 20 representative markets was made to obtain information for improving existing markets and offering suggestions in regard to organizing, maintaining, and operating growers' markets. Five municipal, 4 private, and 11 cooperative markets were studied, the markets ranging in size from a small cooperative to the large privately owned Indianapolis market. Three of the markets were primarily wholesale markets. The business of the other markets ranged from 65 to 100 percent retail. The buildings, facilities, plan of operation, etc., of each market are briefly described and suggestions made as to location, type of building, displaying and grading products, etc.

Organization of the Louisville wholesale fruit and vegetable market, H. B. PRICE, C. D. PHILLIPS, and S. E. WRATHEE (*Kentucky Sta. Bul. 368 (1937), pp. 27, figs. 4*).—This is a preliminary report on the study made in 1935 and 1936. The importance of the Louisville market, its organization, the city as a market for locally grown fruits and vegetables, the gardeners' and farmers' market, the number and activity of wholesale dealers, and the extent of inter-city trucking are discussed.

Marketing fruits and vegetables by motor truck in western Maryland, R. RUSSELL and R. W. LENNARTSON (*Maryland Sta. Bul. 407 (1936), pp. 299-375*,

figs. 6).—This study was made to ascertain the extent to which trucks are used in the marketing of fruits and vegetables in the areas studied, the costs involved in the use of trucks, the effects of the use of trucks on marketing facilities and practices, and the cost of all services in marketing fruits and vegetables. Data for the year ended June 30, 1934, were obtained from 90 growers selling in the Baltimore, Md., markets, 60 in the Washington, D. C., markets, and 39 growers in Washington County, Md.

The markets serving each area are described, and growers' opinions and suggestions regarding the Baltimore and Washington, D. C., markets are discussed. An analysis is made of the number of trips made by growers to each market, the tonnage and value of products marketed, the time consumed in different phases of the marketing at each market, and the various marketing costs for all commodities, for individual commodities, and through different marketing channels.

For the 159 growers, marketing costs average \$7.69 per ton, being 27.8 percent of the gross value of the products. Commission fees were 16.1 of the total marketing costs, transportation costs 27.2, container costs 38.1, other selling costs 15.4, and storage 3.2 percent. Total marketing costs for individual commodities varied from 20 to 37.4 percent of the gross value. The costs for the different areas varied from 8.8 percent for asparagus in the Baltimore area to 46.7 percent for apples in the Washington, D. C., area.

The Twin City milk market, O. B. JESNESS, W. C. WAITE, and P. E. QUINTUS (*Minnesota Sta. Bul. 331 (1936), pp. 24, figs. 5).*—The milk market of Minneapolis and St. Paul is described, with tables and charts showing, by years, the fluid sales of pasteurized, raw, and certified milk, 1921-35, and pasteurized and raw cream, 1924-35, in Minneapolis; the seasonal variations in sales, 1923-31; the percentages of sales in different size units; monthly retail prices of milk, 1919-35; range of and average prices paid by distributors per 100 lb. of milk; average annual distributors' margin per quart, 1919-35; etc. Marketing agreements and licenses, public regulation, and producer-distributors are briefly discussed. The membership and organization of the Twin City Milk Producers' Association, its finances, and volume of milk produced; disposition of milk to distributors and surplus milk manufactured, by years 1920-35; the percentages of whole milk used, sold as fluid milk, separated, used in cheese, condensed, and used in ice cream, by years 1926-35; the expenses of operation, seasonal variations in production, monthly prices paid members for 3.5 percent milk, 1919-35, etc., are described. The question as to whether the association should engage in retailing is briefly discussed.

Marketing onions, J. W. PARK (*U. S. Dept. Agr., Tech. Bul. 555 (1937), pp. 88, figs. 22).*—Tables are included showing the acreages and production, 1926-35, by State groups; shipments by States, 1920-35; imports by months, 1930-34, by countries of origin; exports by months, 1930-34; average seasonal farm prices and farm values of onions by States, 1926-35; and average monthly wholesale prices in less than carlots by types or varieties and States of origin in Boston, New York, Philadelphia, and Chicago from 1930-31 to 1935-36. The important onion areas and districts of the United States, varieties and types of onions grown, foreign trade, and the number of the large onion markets of the United States are described. Harvesting, grading, sizing, packing, Federal and State inspection, loading cars, transportation, storage, shrinkage, financing, methods of shipment, movement by months, distribution of shipments, and methods and channels of city distribution are discussed.

Corn futures (*U. S. Dept. Agr., Statis. Bul. 55 (1937), pp. 101, figs. 4).*—This bulletin supplements that previously noted (*E. S. R., 70, p. 855*) by the addition

of data as to volume of trading, open commitments, and prices from January 3, 1933, to December 31, 1935.

Grade, staple length, and tenderability of cotton in the United States, 1928-29 to 1934-35 (*U. S. Dept. Agr., Statis. Bul. 56* (1937), pp. 63, figs. 11).—This bulletin continues the series previously noted (*E. S. R.*, 75, p. 273). Detailed tables by States, districts of States, and specified periods of the ginning season are included for the 1934 crop and more general tables for the preceding years.

Quality of cotton ginned in Mississippi, crops of 1928-34, W. B. LANHAM, F. H. HARPER, and M. DODSON (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1937, pp. [2]+38, figs. 11).—This study was made in cooperation with the Mississippi Experiment Station. In analyzing the data the State was divided into 4 areas with 18 districts on the basis of similarity of conditions affecting quality of cotton. Tables, charts, and maps are included showing for the United States, Mississippi, and each district by years the amounts—bales and percentages—of cotton of different grades and staple lengths.

For the 6-yr. period an average of nearly 79 percent of the Mississippi cotton crop was extra white, white middling, or above in grade as compared with 68 percent of the upland cotton crops of the United States. The average staple length was 16.7 sixteenths inch for Mississippi and 15.32 sixteenths inch for the United States. The proportion of ginnings in Mississippi grading extra white and white middling and above decreased and the proportion of $1\frac{1}{2}$ in. and shorter staple also decreased as the season advanced.

Quality of Texas cotton, crops of 1928-35, W. B. LANHAM, G. E. MILLER, and N. L. GORDY (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1937, pp. [2]+61, figs. 11).—This study was made in cooperation with the Texas Experiment Station. In tabulating and analyzing the data the State was divided into 11 general soil areas with further division into subareas. The soil types and climatic conditions of the soil areas are described. Tables and charts are included and discussed showing the staple lengths and grades of cotton in the United States, Texas, and the different areas and subareas, 1928-35. An analysis is also made of the staple length and grade of Texas cotton by ginning periods.

The average staple length for the 6-yr. period was 15.32 sixteenths inch for the entire United States crop and 15.04 sixteenths inch for the Texas crop. The grade was approximately the same for the United States and Texas. The average staple length in Texas varied in soil areas but the grade in general was fairly uniform. Staple length became less and grade decreased as the ginning season progressed.

Crops and Markets, [June 1937] (*U. S. Dept. Agr., Crops and Markets*, 14 (1937), No. 6, pp. 109-128, figs. 2).—In addition to the usual crop and livestock production and market reports, seasonal reports are included on the condition of important crops, the reduction in cotton yields from stated causes, and the stocks of barley and rye on farms, June 1. Revised estimates for cotton, 1935-36, and cottonseed, 1936, are also included.

Revised estimates of sweet potato acreage, yield per acre, and production, 1868-1923, C. M. PERVES, D. F. CHRISTY, G. BURMEISTER, ET AL. (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1937, pp. 30).—Tables for the United States and for geographic divisions and States are included. The United States estimates of production included 19 States in 1868 and 22 in 1918-23.

First annual report on tobacco statistics (with basic data) (*U. S. Dept. Agr., Statis. Bul. 58* (1937), pp. 148, fig. 1).—This is the first of a series of annual reports required by the amendment to the Stocks and Standards Act approved August 27, 1935. "In this report effort has been made to have the statistics as complete as possible so far as recent history is concerned, and fairly

comprehensive as to the range of subjects covered, with the expectation that future issues will be restricted to current and relatively recent years. Under this plan this report may be regarded as of permanent value for reference purposes, future issues to be in the nature of supplements." A brief classification of leaf tobacco covering classes and types and a map showing the tobacco-growing districts of the United States are included. Tables cover the acreage, production, and farm value of tobacco in the United States by classes, types, and States, foreign production by countries and classes, prices by weeks and seasons for different types and grades, stocks by types and grades by quarter years, leaf tobacco used in manufacture, tax-paid withdrawals by products and months, per capita consumption in different forms in the United States and European countries, exports for the United States of leaf tobacco by types and countries and of products, imports of leaf tobacco by classes and of products by countries, tariff rates on imports into the United States and into other countries from the United States, taxes and revenue in the United States, railroad and ocean transportation rates, and data as to the number of contracts, processing tax rates, tax collections, etc., under the AAA.

Statistical analysis of the annual average f. o. b. prices of California canned apricots, 1926-27 to 1936-37, H. R. WELLMAN (*California Sta. Mimeogr. Rpt. 60 (1937), pp. 8, fig. 1*).—An analysis is made of the average relationships between f. o. b. prices of canned apricots and total shipments of California canned apricots and index of prices of competing canned fruits. "An increase in total shipments of canned apricots from 2,500,000 cases to 3,000,000 cases has been accompanied by a decrease of 21 ct. a case in the average f. o. b. price, and vice versa, and an increase in the index of competing canned fruit prices from 70 to 80 has been accompanied by an increase of 59 ct. a case in the average f. o. b. price, and vice versa."

Wholesale prices received by farmers for whole milk, 1909-1936, R. E. JOHNSON (*U. S. Dept. Agr., Bur. Agr. Econ., 1937, pp. 60*).—Tables show for the United States and different geographic districts and States the average monthly prices, August 1909 to December 1936, inclusive, received by farmers for whole milk sold at wholesale.

Fats, oils, and oleaginous raw materials: Production, prices, trade, disappearance in the United States, 1912-35, and available data for earlier years, A. DEWEES (*U. S. Dept. Agr., Statis. Bul. 59 (1937), pp. 123*).—The classification of fats and oils is described. Tables cover the production, imports, exports, prices, stock, and disappearance of the different vegetable oils, animal fats and oils, marine animal oils, and the raw materials for such fats and oils. Other tables show tariff rates and excise taxes on and weights and measures of different fats and oils; the saponification value, iodine number, melting point, and titer for leading fats and oils; and the percentages of the more important fatty acids in commonly used fats and oils.

RURAL SOCIOLOGY

Outlines of a rural research program for Utah, L. NELSON (*Utah Acad. Sci., Arts, and Letters, Proc., 13 (1935-36), pp. 27-30*).—The author presents as pressing problems the conservation of natural resources, land use, wildlife, and population relative to natural resources. Without neglecting the older research in the physical and biological fields, he would emphasize the human-economic and social problems of Utah. He points out the importance of teamwork and lists some of the institutions and agencies engaged in agricultural research in the State.

Movements of rural population, C. E. LIVELY (*Ohio Sta. Bul. 579 (1937), p. 106*).—An analysis of the vital statistics of the rural population of the State is

noted which shows that the number of rural births has been declining steadily since 1924 and that the natural increase of the rural population has declined correspondingly.

Rural trends in depression years: A survey of village-centered agricultural communities, 1930-1936, E. DES. BRENNER and I. LORGE (*New York: Columbia Univ. Press, 1937, pp. XVI+387*).—This report of a third survey of 140 village-centered agricultural communities in the United States (E. S. R., 53, p. 385; 69, p. 299) opens with a summary of the basic changes in and adjustments of agriculture from 1930 to 1935, as shown by the census and illustrated in the communities studied. There follows an analysis of changes in population and in communities as such and in the relations of village to country. The discussion then turns to changes in institutions such as those of trade, industry, banking, education, religion, and social life. In connection with education, special attention is given to the rise of adult education during the depression years. Finally, consideration is given to the question of relief, a phenomenon previously almost nonexistent in these communities.

Family life cycle analysis, C. P. LOOMIS and C. H. HAMILTON (*Social Forces, 15 (1936), No. 2, pp. 225-231, fig. 1*).—"Since our time is one of great change, it is doubtful if there are many farm areas in the western world where the cross-section method can give exactly a true picture of the life cycle of the farm family in the generalized sense. However, the comparative analysis here presented, even though supported by an insufficient number of cases, leads the authors to the conclusion that the cross-section method is useful in the analysis of family living data. In certain areas where there have been no great changes in social and biological factors affecting the family, a relatively accurate picture of the historical life cycle of the farm family may be secured by the make-shift method—the cross-section analysis."

The rural family, D. SANDERSON (*Jour. Home Econ., 29 (1937), No. 4, pp. 223-228*).—In this abridgment of a lecture at Teachers College, Columbia University, the author emphasizes the need of giving consideration to the rural family, pointing out that the rural family, particularly the farm family, is much more vital than the urban family and also much larger and more stable.

The depression has called attention to the greater degree of security enjoyed by rural families. Over one-fifth more rural families own their own homes than do urban families. On farms, from one-third to one-half of the family living comes from the farm. Nearly 64.5 percent is in the form of food raised, about 30 percent is the value of house rent, and about 6 percent is in fuel.

The increasing urbanization of rural life is affecting the rural family as well as all other phases of rural culture. Birth rates are declining, paternal control is decreasing, and individual attitudes rather than familistic control are increasing. The changes in family life which are making for the better development of human personality are affecting the rural family, but this evolution will be slower in the country where family relationships will of necessity be adapted to the more elemental conditions of rural life.

Education of farm owners and tenants in Tennessee, C. E. ALLRED and B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 25 (1937), pp. III+40, figs. 37*).—It is concluded that the educational status of farm operators in different areas of the State varies considerably in surveys made but a few years apart. In almost all of the 22 counties studied, over three-fourths of the white farm operators have not attended high school. This percentage is above 95 in 3 counties. The percentage of farm operators with no formal education whatever ranges from none in Madison County in 1920 to 29.5 in Monroe County in 1925. In a survey of Overton County in 1936 about

10 percent of the operators have not attended any school. Few of the operators in any of the surveys have attended college.

In practically every farm survey the educational status of white farm owners is higher than that of white farm tenants. The reverse appears to be true among Negroes, farm tenants being better schooled than owners.

Farm operators under 44 yr. of age have better education than those who are 45 yr. of age or older.

FOODS—HUMAN NUTRITION

The staling and keeping quality of bread, J. B. HUTCHINSON (*Res. Assoc. Brit. Flour-Millers Spec. Rpt. 15 (1936), pp. 27*).—The report consists of a detailed discussion of the research work on bread staling carried out in various countries and the results of investigations made in the laboratories of the association during the past year. An introduction and summary are given by E. A. Fisher. The following topics are discussed: Crust staling; crumb staling, which includes chemical staling and the development of crumbliness and hardness; keeping quality, which is characterized chiefly on staling by loss of aroma and flavor, the development of a dry sawdustlike taste and the actual hardness, crumbliness, and condition of the crumb at the time of eating; and the loss of water, or "drying out." The following practical aspects of the preservation of keeping quality are discussed: The refreshing of bread by heat, the use of hot and cold storage, the advantages of wrapping bread, and the influence of factors such as the kind of flour, the water absorption power, the mixing and manipulation of the dough, the type and degree of fermentation, the length of the baking period, and the addition to the flour or dough of substances which interfere with bread staling or act as bread improvers. None of the substances tested are recommended for use as satisfactory inhibitors of the staling process.

"In conclusion it may be emphasized once more that keeping quality is at a maximum in bread made from good flour of ample gassing power, good gluten content and quality with correct absorption, dough manipulation, and fermentation."

Relation of the age of bread to the amount eaten, M. C. MARKLEY (*North-west. Miller, 186 (1936), No. 1, p. 133; abs. in Minnesota Sta. Rpt. 1936, p. 31*).—The bread consumption is recorded of a family of five, including two adults and three small children, over a period of 7 weeks during which six loaves of bread, alternately white and graham, were delivered fresh from the oven once each week. The white flour used in both breads was a high protein spring wheat patent, which gives bread of very good keeping qualities, and the formula was of medium richness.

The average daily weights of bread consumed on the first day and for 4 consecutive days thereafter were 13.64, 9.34, 8.76, 8.21, and 7.42 oz., respectively. The decreased consumption of bread with increasing age is thought to afford one explanation for the general decline in bread consumption. Attention is called to the changes which have taken place in the commercial production and distribution of bread from the time of local bakeries with prompt delivery of unwrapped bread to the present system of centrally located plants distributing wrapped bread (necessitating a delay of several hours) over considerable distances. Improvements in the effectiveness of the distribution system so as to put fresher bread on the consumer's table is recommended as a means of increasing bread sales.

The availability of the proteins and inorganic salts of the green leaf, M. K. HORWITT, G. R. COWGILL, and L. B. MENDEL (*Jour. Nutr., 12 (1936), No. 3, pp. 237-254, fig. 1*).—In a series of in vitro digestion experiments on dried

spinach, the validity of various food analysis technics was studied, and some modifications were devised.

A method of procedure for estimating the available nitrogen was devised, in which the fat-soluble nitrogen was eliminated by extraction with an alcohol-ether mixture and the nitrate, amide, and ammonia nitrogen were boiled off before determining the protein and amino acid nitrogen. The application of this method gave 3.55 percent available nitrogen as compared with 4.41 percent total nitrogen in the dried spinach tissue.

Chemical analyses gave the amounts of calcium, phosphorus, iron, and chloride in dried spinach as 1.016 ± 0.006 , 0.886 ± 0.002 , 0.0541 ± 0.0002 , and 1.267 ± 0.004 percent, respectively. Determinations by digestion experiments, using various digestive agents, showed the following percentage amounts of available inorganic constituents present in dried spinach: 99.5 percent chloride, 8.6 calcium, 96.6 phosphorus, and 9 percent iron by water extraction; 29.1 percent calcium, 80.6 phosphorus, and 18.6 percent iron by $N/10$ hydrochloric acid; 30.5 percent calcium, 82.5 phosphorus, and 40 percent iron by $N/10$ hydrochloric acid plus pepsin; 100 percent chloride, 12.5 calcium, 90 phosphorus, and 24 percent iron by sodium bicarbonate plus trypsin; and 30.2 percent calcium, 39.9 phosphorus, and 40.6 percent iron by digestion with pepsin followed by trypsin. It is of interest to note that the addition of pepsin to the hydrochloric acid reagent increased the amount of iron available in spinach from approximately 20 to 40 percent.

The chemical composition and nutritive value of potatoes, M. E. WHALLEY (*Ottawa: Natl. Res. Council Canada, 1935, pp. 81*).—This mimeographed report presents a review of the literature, with 191 references.

Culinary quality of potatoes produced in Ohio, H. McKAY and M. B. PATTON (*Ohio Sta. Bul. 579 (1937), pp. 98, 99*).—This is a progress report of studies on the effects of variety, type of soil, and time of planting on the culinary quality of potatoes. Data are included showing a definite positive correlation of the specific gravity of samples tested with scores for texture.

The composition of tubers of sprayed and unsprayed potato plants in relation to cooking quality, E. O. and M. T. MADER (*Amer. Potato Jour., 14 (1937), No. 2, pp. 56-59*).—These studies, reported from the [New York] Cornell Experiment Station, were made with the variety of potato known locally as Heavyweight, a potato of the Rural group, grown in western New York during the season of 1935. Samples were selected at random at intervals during the growing season from unsprayed plants and plants which had been sprayed with bordeaux mixture in amounts calculated to furnish a total of 74 lb. of copper to the acre during the season. The tubers were thoroughly cleaned, ground to a pulp with a food chopper, and well mixed before sampling. The analyses included total nitrogen, reducing sugars, sucrose, starch, copper, iron, crude fiber, and tyrosine.

On corresponding dates of sampling tubers from the sprayed plants showed higher percentages of sugars, starch, and copper and a lower percentage of total nitrogen than those of unsprayed plants. The amount of copper in the tubers from the sprayed plants decreased with successive sampling and that from the unsprayed increased. Analyses of samples on the date of final digging showed no great difference in dry weight, crude fiber, and ash content of the unsprayed and sprayed, but the tubers of the sprayed plants contained strikingly less tyrosine and iron than those from the unsprayed. The values on the dry basis (average of four analyses) were iron 0.0483 and 0.0715, and tyrosine 0.422 and 0.667 percent for the sprayed and unsprayed samples, respectively.

Inasmuch as it has been shown by Tinkler (*El. S. R., 67, p. 183*) that phenolic compounds (in this case tyrosine) and iron are partially responsible for the

blackening of cooked potatoes, the conclusion is drawn that spraying potato plants with bordeaux mixture is of value in counteracting this condition.

The problem of causes of blackening in cooked potatoes, W. E. TOTTINGHAM, R. NAGY, and A. F. ROSS (*Amer. Potato Jour.*, 13 (1936), No. 11, pp. 297-309, figs. 4).—In this investigation at the Wisconsin Experiment Station, the blackening of potatoes on cooking was found not to be correlated with immaturity, storage temperature, or degree of aeration. Slight differences in nitrogen content (1.87 percent of the dry matter of peeled tubers for those which blackened as compared with 1.69 percent for those which remained white) were found in the analyses of a considerable number of samples, but these averages were obtained from wide and overlapping ranges. The average amounts of free α -amino nitrogen, tyrosine, and tryptophan increased appreciably on cooking in the normal potatoes but remained about the same in those which blackened. The relative instability of the proteins in the abnormal potatoes, as suggested by these observations, was confirmed by the results obtained on mild hydrolytic treatment with sodium hydroxide and by enzyme hydrolysis of extracts of the potatoes. In each case the amount of tyrosine liberated was higher in the potatoes which blackened than in the normal samples. Sap from potatoes which blackened was found to be considerably more active in the oxidation of tyrosine into precursors of the pigment melanin.

Because of the known function of potassium as an agent in protein condensation reactions, a comparison was made of the available potassium content of the soil with the discoloration on boiling of potatoes in the 1935 crop. A general relation of discoloration to potassium deficiency in the soils was shown irrespective of the variety of the potato. This also held for potassium content of the potatoes grown in the greenhouse on a synthetic sandy soil, with and without heavy potash fertilizer. Samples containing less than 1.8 percent K_2O in the dry matter showed a general tendency to blacken after cooking.

Experimental results on the preservation of fruits and vegetables by freezing: A progress report, E. H. WIEGAND (*Oregon Sta. Circ.* 122 (1937), pp. 14).—This publication, which is essentially a reprint of Circular 116 (E. S. R., 75, p. 719), has been issued in response to increasing demands for information. Of particular value to housewives are the frozen fruit pack and frozen vegetable pack tables, which summarize methods of preparation, types of container, and method of packing for berries, cherries, and other fruits, and various vegetables.

The use of honey as the sweetening ingredient in cakes, H. MORGAN (*Jour. Home Econ.*, 29 (1937), No. 1, pp. 45-48).—This investigation, carried on at the University of California at Davis, was made to determine the maximum amount of honey that would replace sugar in a basic plain cake formula, whether several varieties of California honeys could be used interchangeably, and whether cakes made with honey retain moisture longer than cakes made with sugar. The basic formula contained sugar 200 g, milk 206.3, fat (Crisco) 113.4, flour 210, baking powder (S. A. S. phosphate) 8.5, salt 3, vanilla 4.4, and eggs 92.1 g. It was estimated that 261.8 g of honey was equivalent to 1 cup of sugar, and that for each such substitution the amount of milk should be decreased by 46.3 g.

In preliminary tests with star-thistle honey the honey could be used in amounts up to 50 percent of the total sweetening without modifying the basic recipe other than adjusting the liquid ingredients, but above this level the cakes were heavy and yellow and had a pronounced astringent flavor. It was found that the undesirable qualities were due to the acidity of the honey, and when this was exactly neutralized with soda cakes in which 75 and

100 percent of the total sweetening was honey could not be distinguished from those made with sugar.

Various California honeys were analyzed for free acid and then used in the same basic cake formula, with honey replacing 50 percent of the sugar and enough soda added to neutralize the acidity. There were no differences in texture and lightness, but the flavor of the cakes made with the strongly flavored honeys, such as resin weed, eucalyptus, buckwheat, star-thistle, and cotton, was less delicate than that with the milder flavored honeys. The addition of spices is recommended to improve the flavor of cakes made with the strongly flavored honeys.

Cakes made with honey were found to retain their moisture longer than those with sugar in proportion to the honey content. Regardless of the kind of honey the moisture content was highest on the third day after baking.

Decisions of courts in cases under the Federal Food and Drugs Act, M. G. WHITE and O. H. GATES (*Washington: U. S. Dept. Agr., 1934, pp. X+1546*).—This volume contains a compilation of approximately 370 court decisions and an accompanying digest. The Federal Food and Drugs Act of 1906 and amendatory and supplemental enactments are given in the introductory chapter.

Foods and drugs, E. R. TOBEY (*Maine Sta. Off. Insp. 163 (1937), pp. 143-156*).—The analytical data included in this annual report (E. S. R., 76, p. 272) consist chiefly of the results of an examination of 77 samples of oils used in packing sardines for refractive index at 25° C., percentage of free fatty acids, iodine number, and cold test.

Bacteriological examination of glassware or china for sanitary quality, C. R. FELLERS, A. S. LEVINE, and E. W. HARVEY (*Amer. Jour. Pub. Health, 26 (1936), No. 12, pp. 1211-1214*).—This contribution from the Massachusetts Experiment Station describes in detail a proposed standard swab method for the bacteriological determination of the sanitary quality of drinking glasses and utensils, with specific directions for preparing the sampling tubes, taking and handling the samples, and recording results.

It is said that if the technic is followed carefully from 40 to 80 percent of the organisms present are recovered, and that the method is sufficiently rapid and simple to be of use in a routine way by health laboratories in checking the sterilization of utensils in food and beverage dispensing establishments.

Nutrition investigations (Connecticut [New Haven] Sta. Bul. 393 (1937), pp. 172, 173).—This progress report (E. S. R., 75, p. 424) summarizes a comparison of the new salt mixture developed by the station with the Osborne-Mendel mixture as a constituent of various types of diets for experimental rats, a study of the effect of repeated pregnancies and lactations on the bone ash of mother rats, a repetition with modern type diets of the earlier experiments of Osborne and Mendel in which tryptophan and lysine were demonstrated to be essential constituents of the animal diet, and a continuation of the experiments, with the cooperation of L. G. Rowntree, on rats on the effects of injections of thymus extracts.

An improved technic for metabolism studies in pre-school children with a statistical determination of its reliability, J. E. HAWKS, M. DYK, and M. M. BRAY (*Jour. Nutr., 13 (1937), No. 1, pp. 51-64, fig. 1*).—In this contribution from the Michigan Experiment Station the technic followed in an extensive series of metabolic studies conducted on preschool children is described and discussed in considerable detail. The investigation was conducted in two experiments, the first on two boys 4½ yr. of age and the second on three girls 3 yr. and two boys 4 and 4½ yr. of age. The purpose was to find the variations in the nitrogen, calorie, and mineral utilization of children of this age receiving a constant diet containing 3 g of protein per kilogram of body weight, the changes

in metabolism when the protein was increased to 4 g per kilogram of body weight, and the interrelationships between the utilization of the various substances.

Tabulated data are included on the physical measurements of the six subjects at the beginning and end of the experimental period, the diet calculations for the medium and high protein diets, and the range and variability in composition (calories, nitrogen, calcium, and phosphorus) of identical diets and of duplicate diets. The latter data show that in spite of great care in the sampling and analysis of foods the composition of the diets containing the same food and prepared under standard conditions varied not only from period to period but also between duplicate diets collected on the same day. The coefficients of variation ranged from 1.2 to 2.8 for the duplicate samples of the same diet and from 1.6 to 3.1 for identical diets.

"The variation in the composition of the food is an unavoidable part of every metabolism study, and it seems probable that the metabolic responses of the subjects would reflect these variations in diet. Since the differences would not be the same in successive experiments in one laboratory or in experiments in different laboratories, it is probably necessary to determine the fluctuations in every experiment."

Effect of diet on the constancy of the urinary nitrogenous constituents excreted daily by pre-school children. J. E. HAWKS, M. M. BRAY, and M. DYE (*Jour. Nutr.*, 13 (1937), No. 2, pp. 179-192, fig. 1).—This paper reports the data obtained in the investigation noted above as to the urinary constituents following a 10- or 12-day preliminary period during 21 consecutive days when the children received 3 g of protein per kilogram of body weight and during the following 15 or 24 days when they received 4 g of protein per kilogram of body weight. The data, which are tabulated separately for the 3-g and 4-g protein periods but, combined for the two series, giving values for 5 children on the 3-g level and 6 on the 4-g level, are discussed chiefly from the standpoint of variability.

"Uric acid in one experiment and creatine in both were about twice as variable as diet nitrogen, while ammonia, acidity, and amino acid showed more irregularity. The increase in the protein content of the diet caused the value for total nitrogen, urea, ammonia, and creatine to be more variable, especially during the first 9 days. Then the figures reached an equilibrium similar to that on the first diet. Therefore, in this study a 9-day preliminary period seemed to be adequate. The change in diet did not seem to influence the variability of the data for acidity, uric acid, amino acid, or creatinine. Individual children tended to react in a similar manner both to the constant diet and to the change in the protein content of the diet."

Milk modification and infant constitution. I. N. KUGELMASS (*New England Jour. Med.*, 215 (1936), No. 27, pp. 1285-1291).—Comparative studies are reported on the relative value of various standard formulas and individualized formulas based upon the body build and condition of the individual infants in the group during the first 3 mo. of life. Each group consisted of from 50 to 60 infants, and the formulas included whole boiled milk, half-diluted boiled milk, evaporated milk in 1:2 dilution, and powdered whole milk and powdered lactic acid milk, respectively, in the proportion of 1 tablespoonful to 2 oz. of water. Each formula was reinforced with 10 percent carbohydrate, and orange juice and cod-liver oil were introduced in the third week in appropriate amounts. A group of breast-fed infants served as controls.

The maximum food consumption and maximum gains in weight were on the individualized formulas. Infants on breast feedings and on processed milk feedings gained more rapidly than those on fresh milk mixtures, and the least number of digestive disturbances was observed on breast feeding and on

individualized formulas. Infants of the linear type required about 70 calories per pound of body weight and tolerated concentrated mixtures, while those of the lateral type required only about 55 calories per pound and tolerated dilute mixtures better than concentrated.

In the author's opinion the type of feeding selected should be on the basis of the digestive capacity of the individual infant rather than the type which least utilizes digestive mechanisms, with fresh milk mixtures the choice for infants that can tolerate them and processed milk mixtures for those with diminished digestive capacity.

Milk allergy in elementary school children.—A preliminary report, D. A. WILLIAMS (*Brit. Med. Jour.*, No. 3960 (1936). pp. 1081, 1082).—Among 150 school children who had refused or shown a disinclination to take milk supplied at school, 88 were found whose refusal was because of allergic manifestations of some kind following the ingestion of milk. In all but one of their families there was a history of allergy. There were 36 children who had no nausea or unfavorable symptoms after taking the milk, but who disliked it both at school and at home, and of these, all except 4 showed a personal or family history of allergy. Of the remaining children, 12 had no symptoms of allergy after consuming milk, but disliked the taste of the pasteurized milk, and 14 refused milk for various reasons unconnected with health or dislike of milk. Only 5 of the group of 12 and 2 of the group of 14 had a family history of allergy.

Although the number included in this preliminary investigation was admittedly too small to permit drawing definite conclusions, the results are considered significant enough to warrant caution in forcing milk upon children unwilling to take it. "While the popular movement to encourage the widespread consumption of milk has much to commend it, the fact that all people cannot take it with impunity should be remembered. Those who are allergic to it must avoid it or suffer."

An inquiry into the drinking habits of children of school age, with special reference to milk drinking. N. C. WIGERT (*Hannah Dairy Res. Inst. Bul.* 7 (1936), pp. IX+10-50, fig. 1).—The information was collected by a memory test given to 13,317 school children. Of this number 52.7 percent did not drink any milk, 32.4 drank milk once daily, 11.6 twice, and 3.3 percent three times or more daily. Tea was taken at least once daily by 94.5 percent. For every time that milk was taken once the poor urban child took tea between 5 and 10 times, the artisan urban child 3 times, and the suburban child twice. Coffee and cocoa were taken rarely, as were beverages such as Oxo, Bovril, Ovaltine, and aerated and mineral waters. The relatively new milk-in-school scheme apparently has tended to popularize milk drinking.

Higher resistance of rats fed casein than those fed vegetable protein. E. S. ROBERTSON and M. E. DOYLE (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 374-376).—The resistance of rats receiving an 18-hr. broth culture of *Salmonella enteritidis* by intraperitoneal injection was studied. The diets contained cornstarch, Crisco, cod-liver oil, wheat germ, and salt mixture and from 13.1 to 13.9 percent of protein in the form of gluten, soybean, or casein. A definitely high resistance to infection was noted in the casein-fed rats and a low resistance in the gluten- and soybean-fed rats.

Further studies on the calcium content of the body in relation to the calcium and phosphorus content of the food. L. B. WHITCHER, L. E. BOOHER, and H. C. SHERMAN (*Jour. Biol. Chem.*, 115 (1936) No. 3, pp. 679-684).—The authors studied the problem of optimal calcification in two series of experiments on rats. In series 1 the diets contained 0.43 percent of phosphorus and 0.53, 0.7, 0.84, or 1.04 percent of calcium, with calcium:phosphorus ratios of 1:2, 1:6, 2:0, and 2:4, respectively. In series 2 the diets contained 0.73

percent of phosphorus, with 0.55, 0.71, 0.89 or 1.05 percent of calcium and calcium:phosphorus ratios of 0:7, 1:0, 1:2, and 1:4, respectively. The relative nutritional effects of these diets through a considerable portion of the life history of the animals was compared in terms of growth, calcium content of the bodies, and skeletal development as measured by body lengths at definite ages.

The increased amounts of calcium in the diet did not bring about any distinct increase in the rate of calcification of the body, while the increased phosphorus induced only slight increases. The animals on the different dietaries showed no significant differences in body length at a given age.

Availability of iron in wheat, A. H. FREE and F. C. BING (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 453, 454).—Eleven samples of hard spring and soft winter wheats were analyzed for total and inorganic iron, using a modification of the Elvehjem technic (E. S. R., 71, p. 130) to determine inorganic iron and the thioglycolic acid method for total iron, as described by Hanzal (E. S. R., 70, p. 154). Biological assays were made on samples of Trumbull and Nabob soft winter wheats.

The total iron ranged from 2.9 to 4.87 mg and the inorganic iron from 2.46 to 4.04 mg per 100 g of wheat, an average of 81 percent of the total iron. Hemoglobin determinations made on the rats receiving wheat as a supplement to the anemia-producing milk diet demonstrated an actual increase in hemoglobin concentration for the 4-week period of from 9.1 to 10.1 g per 100 cc of blood, showing that the iron of wheat is well utilized for hemoglobin formation.

A comparison of oral administration versus intraperitoneal injection of colloidal iron upon blood regeneration in nutritional anemia of the rat, H. H. BEARD and T. S. BOGESS (*Amer. Jour. Physiol.*, 118 (1937), No. 2, pp. 211–216).—Young rats made anemic by subsistence on a cow's milk diet containing an average of 0.11 mg of copper per liter were fed or injected intraperitoneally with different amounts of a colloidal copper-free iron preparation until blood regeneration was complete.

The injection of 2 mg of colloidal iron weekly for 4 weeks (8 mg) was as effective as the ingestion of the same amount daily by mouth for 3 weeks (42 mg). The injection of 0.26 mg every other day for 3 weeks (2.73 mg) was as effective as the ingestion of that amount daily for 5.5 weeks (10 mg). The utilization of colloidal iron by injection was 28 percent for the 8-mg dose and 87 percent for the 2.73-mg dose and by mouth was 6 percent for the 42-mg dose and 22 percent for the 10-mg dose. It is estimated that the minimum daily dose of injected iron required for hemoglobin regeneration is 0.13 mg. It is concluded that inorganic iron alone is very effective in blood regeneration in nutritional anemia of the rat.

Fluorides in Foochow waters and dental defects, T. H. WANG (*Jour. Chin. Chem. Soc.*, 4 (1936), No. 3, pp. 172–177, fig. 1).—The fluorine content of 139 samples of water in Foochow was determined by the Sanchis method.

That the toxic concentration of fluorine is associated with dental defects was demonstrated by the presence of the deeply stained and pitted type of mottled enamel in the teeth of the villagers drinking water from the shallow wells having a fluorine content between 0.7 and 7 p. p. m. Hot spring water had a fluorine content averaging 9 p. p. m., deep hot water wells 9.6, and spring water 0.6 p. p. m.

Natural sources of fluorine and "mottled teeth" in Maldon, Essex, J. H. BOWES and M. M. MURRAY (*Nature [London]*, 137 (1936), No. 3472, p. 328).—Data are tabulated on the fluorine content of samples of drinking water from London and from Maldon, Essex, the only region in England where mottled teeth had been recognized. Pond water from London contained 0.5 and from

Maldon 1.2 p. p. m. of fluorine, main water from London 0.5 and well water from Maldon 5 p. p. m. Samples of grass from London contained 0.0001 and from Maldon 0.0003 percent and the teeth of wild rabbits from Surrey 0.0053 and from Maldon 0.0283 percent.

"That very low concentrations of fluorine in drinking water can be effective might be explained by the fact that simultaneously fluorine is being ingested in plant and animal foodstuffs. Though such sources are less important, they should be considered as possible contributory sources. The reason why acquisition through the water supply has seemed to be the all important is no doubt due to the fact that the fluorine in water occurs as sodium fluoride, whereas in foodstuffs it more likely occurs combined with calcium, in which combination it is known to be less toxic."

Some observations on the development of the teeth of *Cavia cobaya*, M. T. HARMAN and A. SMITH (*Anat. Rec.*, 66 (1936), No. 1, pp. 97-111, pls. 2).—This investigation with normal guinea pigs from the earliest stage of formation until adult size was undertaken to establish a basis for comparison in the use of guinea pigs in nutrition studies, particularly vitamin C.

The material studied consisted of about 80 embryos varying in copulation age between 20 and 68 days and a number of postnatal animals from 1 to 40 days of age, both being studied by microtome sections and dissections made under the binocular microscope. The description of the chronological development of the teeth is supplemented by a number of microphotographs.

Liver oil from *Dasyatis akiei*: Vitamin contents, physical and chemical constants, T. H. WANG and C. H. KAN (*Jour. Chin. Chem. Soc.*, 4 (1936), No. 5, pp. 393-401, figs. 3).—In addition to the analysis of the fatty acids content and the determination of physical and chemical constants of the liver oil of the fanfish (*D. akiei*), the vitamin A and D contents were determined biologically, following the procedure described by Tolle and Nelson (*E. S. R.*, 67, p. 481) for vitamin A and the Steenbock-Black modification (*E. S. R.*, 54, p. 489) of the line test for vitamin D. According to the international standards adopted in 1931, fanfish oil is a rich source of both vitamins, containing approximately 1,000 units of vitamin A and 200 units of vitamin D per gram.

Primary, secondary, and nonspecific effects in experimental vitamin A deficiency in rats [trans. title], T. HAET DE RUYTER and O. ROSENTHAL (*Ztschr. Vitaminforsch.*, 5 (1936), No. 3, pp. 169-185, figs. 6; *Fr., Eng. abs.*, pp. 184, 185).—The findings in a histological study of Bartonella-free rats deprived of vitamin A are reported. It is concluded that the primary manifestations of vitamin A deficiency are the direct result of primary atrophy of the epithelium of the eye and of the mucous membranes of the digestive and urogenital tracts and of the lymphoid tissues. It is suggested that the lowered resistance to infection in vitamin A-deficient rats is due to the atrophy of the lymphoid tissues. Under the indirect secondary effects are listed Bartonella anemia in infected strains of rats and a disturbance of fat metabolism which is probably due to inanition.

Effect of various factors on the vitamin B₁ content of yeast, P. L. PAVCEK, W. H. PETERSON, and C. A. ELYEHJEM (*Jour. Bact.*, 35 (1937), No. 1, p. 100).—The factors studied included three types of media, six strains of yeast, and certain conditions of growth, such as pH, temperature, aeration, etc. The yeasts were grown aseptically in kilogram batches and their vitamin B₁ values determined by biological assay on day-old chicks.

The yields of dry yeast, based on the sugar fermented, ranged from 24 (bakers' yeast B) to 40 percent (bakers' yeast A) on the wort medium; from 28 (*Saccharomyces logos*) to 43 percent (brewers' yeast) on the molasses medium; and from 12 (*Willia anomala*) to 29 percent (brewers' yeast) on the glucose-salts medium. Omitting aeration, raising the pH from 4.3 to 6.0, and

lowering the temperature from 30° to 20° C. decreased the yield of the bakers' yeast on which these factors were studied, with lack of aeration having the most pronounced effect.

Bakers' yeast contained approximately 10 international units of vitamin B₁ per gram of dried yeast when grown on the wort medium, 5 international units on the molasses-salt medium, and 3 international units on the synthetic medium in comparison with from 5 to 13 international units per gram of commercial bakers' yeast. Brewers' yeast, which ordinarily contains about 50 international units per gram, had about the same values as reported for bakers' yeast when grown on the above three media. Other strains gave similar values.

It is concluded that the composition of the medium is the most important factor in determining the vitamin B₁ content of yeasts.

The vitamin C content of the Porto Rico sweet potato, C. L. NEWTON and G. C. LOWRY (*Jour. Home Econ.*, 29 (1937), No. 2, pp. 114-117).—In this contribution from the Georgia Experiment Station, the authors determined the vitamin C content of the Porto Rico variety of sweetpotato grown for two consecutive years on clay loam soil and fed to the experimental animals when freshly dug or after curing by the usual home method in banks of earth and cornstalks. The guinea pigs received a slightly modified form of the Sherman basal diet supplemented by 5-, 10-, and 15-g portions of raw, boiled, and baked sweetpotato, cut so as to include a proportional amount of all parts and fed immediately.

The raw sweetpotato furnished almost complete protection at the 5-g level, indicating a content of slightly less than 0.2 Sherman unit of vitamin C per gram. The boiled sweetpotato was approximately equal to the raw, while the baked sweetpotato was about two-thirds as rich in vitamin C content. At the 10-g level mild scurvy was noted only in the animals receiving the baked potato, with the raw potato giving the highest weight gains. At the 15-g level all the animals were protected from scurvy, and for some inexplicable reason slightly higher weight gains resulted from the baked than from the boiled potato supplements.

Several months' storage seemed to have no appreciable effect on the vitamin C content, and no difference was noted in the content of sweetpotatoes harvested on the same farm in two consecutive years.

Ascorbic acid content of a number of citrus fruits, E. P. DANIEL and M. B. RUTHERFORD (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 9, pp. 689-693).—A number of citrus hybrids, which have been developed by the U. S. D. A. Bureau of Plant Industry as described in Circular 181 (E. S. R., 66, p. 830), were analyzed for ascorbic acid by the Bureau of Home Economics, fruits having been selected and shipped to Washington from the U. S. Horticultural Field Laboratory, Orlando, Fla., and analyzed as soon as possible after arrival.

The ascorbic acid values of the juices of eight varieties of oranges varied from 0.32 to 0.62 mg per cubic centimeter of juice. One of the three varieties of grapefruit had a value of 0.64 mg and the others ranged from 0.33 to 0.38 mg. Two samples of one variety of tangerine gave values of 0.18 and 0.24 and another variety 0.37 mg per cubic centimeter. The range in values for a tangelo (a grapefruit-tangerine hybrid) was from 0.18 to 0.64 mg and the average value for six samples of a single variety of tanger (a tangerine-orange hybrid) 0.4 mg per cubic centimeter. Of the few samples of tangerines, limequats (lime-kumquat hybrid), and orangequats (tangerine-kumquat hybrid) all had relatively low values, on the order of about half that of most of the varieties of oranges tested. Preliminary tests on Perrine lemons (a lemon-lime hybrid), picked both in the ripe yellow and light green stages and kept for 2 mo. in cold storage, indicated practically the same content of ascorbic

acid at the two stages of ripeness, 0.24 and 0.26 mg per cubic centimeter as compared with 0.4 mg per cubic centimeter for freshly picked fruit.

Vitamin C in citrus juices, season 1935-36, J. and T. YOFE (*Hadar*, 9 (1936), No. 10, pp. 230, 231).—The authors studied the amount of vitamin C in the 1935-36 crop of Palestine oranges obtained from one tree during a 3-mo. period, using the Tillmans method based on the titration of 2,6-dichlorophenol-indophenol. The vitamin C content varied from 45 to 53.6 mg per 100 cc of juice during January, from 41.3 to 62.3 mg in February, and from 31.5 to 48.3 mg in March. No constant relationship was noted between the size of the fruit and the amount of vitamin C present in the juice.

Antiscorbutic value of South African mangoes, L. LEVY (*Farming in So. Africa*, 12 (1937), No. 131, p. 90).—In continuation of previous investigations on the vitamin C content of South African products (E. S. R., 76, p. 423), the author determined the antiscorbutic value of 14 varieties of mangoes, using the Birch, Harris, and Ray modification (E. S. R., 69, p. 169) of the Tillmans method. The values obtained varied from 0.072 mg of ascorbic acid per cubic centimeter of juice from a fruit weighing 235 g of the Bombay Green variety to 1.29 mg from a fruit weighing 137 g of the Sabre variety. The concentration of the vitamin would appear to depend upon the variety rather than the size of the fruit.

The relation of vitamin C to the hemorrhagic diatheses, D. J. STEPHENS and E. E. HAWLEY (*Jour. Lab. and Clin. Med.*, 22 (1936), No. 2, pp. 173-179, figs. 2).—The effect of large doses of orange juice was studied in four patients with hemophilia and in two patients with chronic thrombocytopenic purpura. In addition to the regular diet each patient received 100 or 200 mg of vitamin C daily. With one exception the usual diet contained an average amount of antiscorbutic foods. The cevitic acid content of 24-hr. specimens of urine was determined by titration with 2,6-dichlorophenolindophenol according to the method described by Harris and Ray (E. S. R., 73, p. 427), and a modification of the apparatus described by Dalldorf (E. S. R., 70, p. 728) was used to determine capillary resistance. Coagulation and bleeding times were determined.

The case reports indicate that saturation with vitamin C had no demonstrable effect on the hemorrhagic manifestations, since in three patients with hemophilia and in one with thrombocytopenic purpura hemorrhages recurred or continued during the period when large amounts of orange juice were being administered. No significant changes in the number of platelets, bleeding time, clotting time, character of the clot, or in capillary resistance were observed. It is suggested that favorable therapeutic effects may be expected from the administration of vitamin C only in capillary bleeding associated with vitamin C deficiency.

Vitamin C and juvenile rheumatism, with some observations on the vitamin-C reserves in surgical tuberculosis, M. A. ABBASY, N. G. HILL, and L. J. HARRIS (*Lancet [London]*, 1936, II, No. 24, pp. 1413-1417, figs. 3).—In continuation of previous studies (E. S. R., 74, p. 888), following the same method of determining vitamin C and considering an excretion of 13 mg of vitamin C per 10 stone (140 lb.) of body weight as the standard level of excretion, the authors studied 107 cases of active juvenile rheumatism and 86 cases in the convalescent period, with 64 normal individuals receiving the same institutional diet serving as control subjects. The dietary was liberal, with a vitamin C content well above the minimum standard of 25 mg per day per 140 lb. of body weight. Forty-two surgical and 46 quiescent surgical cases of tuberculosis were also studied.

On the basis of a 140-lb. body weight, the average excretion of vitamin C for the control subjects was 20 mg per day as compared with 9 mg for the active rheumatic and 10 mg for the convalescent rheumatic patients. The 23 cases

of surgical tuberculosis averaged 9 mg and the 46 cases of quiescent surgical tuberculosis 19 mg per day of vitamin C excreted from the body.

The administration of test doses of vitamin C confirmed the conclusion that the rheumatic subjects, both active and convalescent, were in a lower state of vitamin C saturation than were the control subjects. When the daily intake of vitamin C was increased by the addition of one-half orange per day per 14 lb. of body weight, the rheumatic subjects took longer to reach a given level of excretion than did the control subjects, and when after 5 weeks the new state of equilibrium had been reached, corresponding with the new diet, the new "resting level" for the rheumatic patients remained markedly below that for the controls. It would appear that "in the rheumatic subjects there is an increased need for vitamin C and probably an increased destruction in the body." This clinical evidence supports the view that vitamin C therapy is likely to be helpful in juvenile rheumatism, both as a prophylactic measure and in the curative treatment.

Recent observations on the biochemistry of the lens, D. R. CAMPBELL (*Brit. Med. Jour.*, No. 3961 (1936), pp. 1133-1136).—In this review the newer methods of producing experimental cataract are discussed. Cataract in experimental animals appears to be inherited as a recessive characteristic and is associated with certain degenerative changes in the retina. In man the predisposition to cataract appears to be transmitted as a true dominant character, but with occasional lapses which are difficult to explain. A nutritive or endocrine disturbance may be an additional requisite factor. Present findings do not show any metabolic changes which may be associated with cataract in man except some slight evidence of a variation in blood calcium content, particularly in endocrine cataract. There is considerable evidence that vitamin C is an important factor.

A list of 40 references to the literature is appended.

The partition of reduced ascorbic acid in blood, D. J. STEPHENS and E. E. HAWLEY (*Jour. Biol. Chem.*, 115 (1936), No. 3, pp. 653-658).—The reduced ascorbic acid content of whole blood, plasma, red blood cells, and white blood cells was determined by titration of trichloroacetic acid extracts with the indophenol reduction indicator according to the method of Birch, Harris, and Ray (*E. S. R.*, 70, p. 741) in 11 leukemia patients, 15 with other diseases, and 4 normal subjects.

The reduced ascorbic acid content of whole blood in the patients with leukemia varied from 1.66 to 5.45 mg percent, in the normal subjects from 0.86 to 1.48, and in patients with other diseases from 0.66 to 1.23 mg percent. In the blood plasma the ranges were, respectively, from 0.91 to 3.75 mg percent, from 1.1 to 1.84, and from 0.7 to 1.2 mg percent; in the packed red blood cells from 0.76 to 6.47, from 0.84 to 1.19, and from 0.72 to 1.33 mg percent; and in the packed white blood cells from 8.12 to 75, from 8.65 to 26.4, and from 6.95 to 20.2 mg percent.

Scurvy as the result of dietetic treatment, R. PLATT (*Lancet [London]*, 1936, II, No. 7, pp. 366, 367).—Records of 4 adults showing typical manifestations of developed scurvy are presented to illustrate the dangers of prolonged treatment with diets lacking in vitamin C. One patient was a neurotic woman who had placed herself on a diet, and the other 3 had been receiving dietetic treatment for peptic ulcer. Fruits and vegetables, except potatoes, were lacking in all the dietaries. Addition of tomato juice relieved the condition in 2 patients, and injections of redoxon were effective in the other 2 cases.

The antirachitic value of irradiated yeast in infants, T. G. H. DRAKE, F. F. TRSDALL, and A. BROWN (*Jour. Nutr.*, 12 (1936), No. 5, pp. 527-533, pl. 1).—The daily administration during 5 winter months of approximately 500 international vitamin D units in the form of irradiated yeast in cooked farina to 69 normally growing infants of British and northern European stock in Toronto, Canada,

prevented in every instance the development of rickets of a moderate or marked degree.

Definite healing of marked rickets in 1 infant was brought about by the daily administration of the irradiated yeast in amounts furnishing 1,000 international units of vitamin D, and of moderate or marked rickets in 4 infants by the administration of 500 units daily for 1 mo.

A study of the fecal flora and the line test of normal rats, rachitic rats, and healing rachitic rats, H. FRIEDMAN (*Jour. Nutr.*, 12 (1936), No. 2, pp. 165-172, figs. 3).—This is a comparative study of the H-ion concentration and bacterial flora of feces of normal rats, rachitic rats, and rats which were healed of rickets by feeding irradiated ergosterol or vitamin D milks. The Steenbock ration No. 2965 was used, with the special sources of vitamin D being given from the nineteenth to the twenty-ninth days of the experimental period.

The results indicate that if the diet is known, the tendency toward rickets or healing in rachitic rats can be judged approximately by means of the basic or acid H-ion concentration of the feces, although the extent of the rickets and of the healing cannot be ascertained without the use of the line test or X-ray examination. When the H-ion reaction was acid, as in the normal and healing rats, the colonies found in the feces were acid-producing. When the H-ion reaction was basic, as in the rachitic rats, the colonies present in the feces were nonacid-producing. The feces of rachitic rats contained fewer *Bacillus coli* than did the feces of normal and healing rats. The addition of vitamin D milks and irradiated ergosterol caused increases in the number of *B. Coli* colonies in the feces.

The effect of vitamin D on intestinal atony of rickets, L. YODER (*Amer. Jour. Digest. Diseases and Nutr.*, 3 (1937), No. 11, pp. 828, 829).—In previous studies conducted at the Iowa Experiment Station (E. S. R., 72, p. 822), it was found that the intestinal reduction of iron in deficient animals was decreased by feeding vitamin D and that the surface tension of the intestinal juice was also decreased by calcifying doses of the vitamin. In this contribution the author studied the effect of the ingestion of from 2.2 to 8.8 mg of viosterol upon the time required for the passage of food through the digestive tract of young rats receiving the Steenbock rickets-producing ration 2965. After 6 days or more on the diet, 1 percent of lampblack was incorporated into the ration and fed at the rate of 2 g per rat at intervals not exceeding the ordinary rate of consumption of the food, and the first appearance of black feces was noted.

The average decrease per litter in the time required for the passage of food through the digestive tracts of the rats receiving vitamin D was 26 percent. Larger amounts of vitamin D did not induce a proportionate decrease in the time of digestion. It would appear that there must be a minimal vitamin D requirement by the digestive tract for a tonicity which can maintain either a decreased intestinal volume or increased motility. "Thus, shorter digestion periods induced by the ingestion of vitamin D may account for the accompanying decreases in the intestinal reduction of iron."

The effect of vitamin D on intestinal iron reduction, L. YODER (*Amer. Jour. Digest. Diseases and Nutr.*, 3 (1937), No. 11, pp. 829-831, figs. 2).—In continuation of the study noted above the author investigated the possibility of determining the decrease in iron reduction in the intestine of rachitic rats receiving vitamin D supplements as a test for vitamin D which might be correlated with both the lowering of intestinal alkalinity and the increased calcification of the bones which follow the ingestion of vitamin D by rachitic rats. A preliminary experiment showed that the effect of vitamin D upon iron reduction was more apparent in the expelled feces than within the digestive tract. Eighteen rats were placed on the Steenbock rachitogenic

ration 2905 supplemented by 0.5 percent of powdered hydrated ferric oxide. On the twenty-fifth to twenty-seventh days, six pairs were given as a supplement to the ration 1, 1.5, 2, 4, 8, and 16 mg, respectively, of viosterol per 100 g of ration for a 10-day period. Determinations of fecal pH and of the ratios of reduced iron to total iron were made.

The ratios of reduced iron and the H-ion concentrations showed similar trends, both being low at the start and showing higher and more constant values as the rickets progressed in the six animals not receiving vitamin D and in the two pairs receiving 1 and 1.5 mg of viosterol. The animals receiving increased amounts of the viosterol supplement showed a decrease in the fecal reduced iron, although bone calcification was noted only at the 8- and 16-mg levels. The reduced iron and the pH of the feces appeared to be more sensitive indicators of the presence of vitamin D than was bone calcification as shown by the line test.

Sprue—a clinical summary, A. C. REED (*Amer. Jour. Trop. Med.*, 16 (1936), No. 5, pp. 499-526).—Included in this discussion of sprue from the standpoint of distribution, predisposing causes, etiology, clinical picture, diagnosis, morbid anatomy, clinical pathology, and treatment is a discussion of the possible relationship of the disease to nutritional deficiencies. Evidence is cited of a conditioned deficiency involving the intrinsic gastric factor for pernicious anemia. To explain why, in the absence of this factor, sprue, pernicious anemia, combined degeneration of the cord, or pellagra may develop, the following suggestion is made:

"There must be another, at present unknown, element in the situation. This may be another deficiency, bacterial or virus infection, endocrine disturbance, or something else. If this unknown conditioning factor precipitates the functional pathology in the posterior tracts of the cord, the result is subacute myelonic degeneration; if in the skin and brain, it is pellagra; if in the blood-forming system, it is pernicious anemia; if in the alimentary tract, it is sprue."

Several case histories are given, and an extensive list of literature references is appended.

HOME MANAGEMENT AND EQUIPMENT

A study of ovens used for domestic cooking purposes, G. M. REDFIELD (*Indiana Sta. Bul.* 416 (1936), pp. 20, figs. 12).—The author compared the radiation losses, operation costs, and temperatures maintained under various conditions of operation, heat retention and distribution, the accuracy of thermostatic controls, and the thermal efficiencies of five standard electric range ovens, one gas range oven using city gas, the same oven equipped with conversion burners and used with bottled gas, and an oven specifically designed for use with bottled gas.

A measurable variation was noted in the radiation losses computed per 1,000 m² of inside oven surface. The electric ovens required less time for preheating and more energy than did the gas ovens, and also showed better heat retention. This indicates that cooking will continue longer after the heat is turned off in the electric ovens tested than in the gas ovens. In all ovens the heat was distributed fairly uniformly and without sufficient variation in temperatures in different parts of the oven to cause variations in the brownness of baked products. The thermal efficiencies in the electric ovens varied from 26.15 to 32.18 percent and in the gas ovens from 14.25 to 18.21 percent. The electric ovens required from 344 to 587 w to preheat to 325° F., from 256 to 485 w to maintain this temperature for 1 hr. with the oven empty, and from 435 to 656 w to bake a sponge cake. In the gas ovens the city gas range equipped with conversion burners required the least expenditure of heat units, followed by the regularly equipped bottled gas range and

the city gas range. The temperature variations for a given thermostat setting were found to be much greater in the electric than in the gas ovens. The gas ovens maintained a more even temperature than did the electric ovens, although either gave satisfactory results.

Introducing the electric range. M. M. MONROE and E. M. COBB (*Maine Agr. Col. Ext. Bul.* 222 (1936), pp. 18, figs. 7).—In this bulletin are presented, in question and answer form, points for the housewife to know concerning the selection and use of an electric range and of cooking utensils.

Evaluation of certain factors affecting the cost of using utensils on electric heating units. M. M. MONROE (*Maine Sta. Bul.* 386 (1937), pp. 53-155, figs. 23).—The author studied the effect of the width of the pan in relation to that of the heating unit, the magnitude of variations in efficiency caused by differences in area of contact, the relative importance of contact between the utensil and the heating surface and the economy of black-bottom utensils as affected by the type of heating unit, the effect of the thermal efficiency of the utensil and heating unit upon the time of maintaining boiling with stored heat, the effect of polished aluminum v. black sides and cover and of the depth of the pan upon heat retention of a utensil, and of the design of a cover upon the amount of water evaporated during heating to boiling and during maintenance of boiling. A tentative study was also made of the relative economy of using duplicate and triplicate sets of saucepans on the same unit and of a "waterless" and a "well" cooker.

The findings are summarized separately for (1) the investigator of thermal efficiency of utensils used on electric heating units, (2) the manufacturer of cooking utensils and of electric heating units, and (3) the housewife as a guide to utensil selection. The last summary is an elaboration of the material contained in the bulletin noted above.

A supplement presents data on the differences in efficiency of utensils and heating units in terms of watt-hours and time required to heat the water and in the amount of water evaporated with a given heat input and in a given length of time during the maintenance of boiling.

MISCELLANEOUS

Report of the director [of the New Haven Station] for the year ending October 31, 1936. W. L. SLATE (*Connecticut [New Haven] Sta. Bul.* 393 (1937), pp. 161-213, fig. 1).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

The Forty-ninth Annual Report of the Maryland Agricultural Experiment Station [1936], H. J. PATTERSON (*Maryland Sta. Rpt.* 1936 pp. XLVIII+690, figs. 89).—In addition to experimental work previously noted or referred to elsewhere in this issue, this report includes reprints of Bulletins 378-396.

Forty-third Annual Report [of Minnesota Station], 1936, A. BOSS (*Minnesota Sta. Rpt.* 1936, pp. 74).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fiftieth Annual Report of [Nebraska Station, 1936], W. W. BUEB (*Nebraska Sta. Rpt.* [1936], pp. 64).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-fifth Annual Report of [Ohio Station], 1936, C. G. WILLIAMS ET AL. (*Ohio Sta. Bul.* 579 (1937), pp. 140, figs. 16).—The experimental work reported not previously referred to is for the most part noted elsewhere in this issue.

List of periodicals currently received in the Library of the United States Department of Agriculture, June 1, 1936, compiled by E. G. HOPPER (*U. S. Dept. Agr., Misc. Pub.* 245 (1936), pp. IV+337).—This list, arranged both alphabetically and by subjects, supersedes earlier compilations (*E. S. R.*, 13, p. 1107; 22, p. 595; 48, p. 694.)

NOTES

Connecticut College and State Station.—B. W. Ellis, director of the extension service, has resigned to engage in farming and has been succeeded by Dr. Roger B. Corbett, senior extension economist of the U. S. D. A. Extension Service.

Dr. George P. Clinton, whose retirement on July 1 as botanist of the State station has been recently noted (*E. S. R.*, 77, p. 432), died August 13 at the age of 70 years. A native of Illinois, he received the B. S. degree from the University of Illinois in 1890 and the M. S. degree in 1894, as well as the M. S. degree from Harvard University in 1901 and the D. Sc. degree in 1902. He served as assistant botanist in the Illinois University and Station from 1894-1900, beginning his work in Connecticut in 1902. In addition to 35 years' continuous service in the station, he was also lecturer in forest pathology in Yale University from 1915 to 1926, and from 1926 to 1929 research associate.

Dr. Clinton was widely known for his many contributions to phytopathological research. He had given special attention to cereal diseases caused by the smuts, tobacco mosaic, the combating of downy mildew, and white pine blister rust, and he was the author of a long list of publications on these and related subjects. He was a member of the National Academy of Sciences, president of the American Phytopathological Society in 1912, and chairman of Section G of the American Association for the Advancement of Science in 1914.

Iowa College and Station.—Dr. Percy E. Brown, associated with the agronomy work of the institution since 1910 and head of the department since 1932, died July 7 at the age of 53 years. A native of New Jersey and the recipient of the B. S., M. A., and Ph. D. degrees from Rutgers University, he served as assistant soil chemist in the New Jersey Stations from 1906 to 1910. In Iowa he gave early and detailed attention to soil bacteriology and soil management, including the development of the soil survey. He had long been active in the American Society of Agronomy, serving continuously as secretary-treasurer since 1920 except for the year 1932 when he was president, and was very successful in upbuilding the membership and finances of that organization. At the time of his death he was also chairman of Section O, Agriculture, of the American Association for the Advancement of Science and editor of the *Iowa State College Journal of Science*.

Massachusetts College and Station.—Dr. F. H. Hesselink van Suchtelen, associate professor of microbiology and research microbiologist from 1913 to 1918, died at Apeldoorn, Netherlands, June 23 at the age of 53 years. He had also served in 1911 and 1912 as research associate in bacteriology in the Michigan Station.

New Mexico College and Station.—Wilson Hall, built in 1907 and housing the departments of agricultural economics, home economics research, and irrigation and the cotton improvement work, was completely destroyed by fire September 5, with much loss of valuable equipment and records.

South Dakota College and Station.—A. M. Eberle, director of the extension service, has been appointed vice dean of agriculture. I. B. Johnson, extension animal husbandman, has been appointed vice director of the station and associate professor of animal husbandry.

EXPERIMENT STATION RECORD

VOL. 77

DECEMBER 1937

No. 6

"BETTER PLANTS AND ANIMALS: A SURVEY OF SUPERIOR GERM PLASM"

Under the above title, the Federal Department of Agriculture has just issued the second and concluding installment of what is thought to be the first comprehensive effort to survey superior germ plasm in the leading farm plants and animals. Undertaken for publication as the dominating theme in the Yearbook of the Department for 1936, the amount of material assembled proved to be so extensive as to occupy not only over 1,000 pages of that volume but more than 1,300 pages in the Yearbook for 1937, as well as several articles and bibliographies omitted for lack of space but available as 1937 Yearbook separates. Taken as a whole, it undoubtedly constitutes the most complete account of the current status of breeding work and genetic research in relation to farm plants and animals which has thus far been prepared. In the words of its sponsor, Secretary Henry A. Wallace, it epitomizes "how much we know and also how much more we should know."

The project was under the direction of a special committee of the Department appointed by the Secretary in 1933 to make "a national and to some extent an international survey of practical breeding and genetic research with those plants and animals that are important in American farming." The first fruits of the work appeared in the 1936 Yearbook as a series of 20 papers dealing chiefly with the major crop plants and classes of livestock. The final contribution, now at hand, is supplementary, covering in 41 papers the broad and varied field remaining. A glossary of genetic terms, a chronology of genetics, and a detailed index are included in the two volumes.

Much of the material was collected through questionnaires designed to survey the work being carried on in all State agricultural experiment stations, similar public institutions abroad, and to some extent in private or endowed institutions and by individuals. The preparation of the papers was assigned to Department specialists, who have not only summarized the information obtained from the survey but have drawn on their own experience and knowledge and the whole field of technical literature. An effort has been made to interest and

inform both the general and the advanced reader. Much space has been given to data showing the organization and status of research projects under way, and lists are appended of plants with superior germ plasm available for future breeding work.

As a foreword by Secretary Wallace points out, "the science of the quality of life as it passes from generation to generation is in many respects the greatest and youngest of all the sciences." The art of plant and animal breeding is an old one, but the science of plant and animal genetics began with the present century. The Yearbooks reveal how rapid and far reaching have been its accomplishments. In the case of plants especially, there have been developed out of the old stock a large number of new forms with better quality, more productiveness, and greater resistance to disease and adversity. Among the outstanding achievements for fruits and vegetables alone which are cited are "the development of the wilt-resistant Marglobe tomato, which is now widely grown and saved the Florida producers from ruin; strains of cantaloups resistant to powdery mildew and of lettuce resistant to brown blight and powdery mildew—both of vital importance to California growers; snap beans resistant to some of the chief diseases that plague producers; cabbages resistant to yellows; sweet corn of such uniform and superior quality that it has remade canning practices; superior varieties of raspberries; blueberries far better than those produced by nature; a large number of improved navel oranges from bud selections; and many interesting new fruits created by hybridizing different kinds of citrus."

Nevertheless, it is made clear that geneticists "would be the first to say that they have hardly scratched the surface. . . . Looking into the future they can see far richer possibilities as their science pushes forward with its exploration and experimenting." One of the major purposes of the survey was to attempt "a frank appraisal of the present situation on a major segment of the agricultural front—not only to sum up achievements but to expose weaknesses and shortcomings. . . . In almost every case, it is shown that we are far short of attaining the objectives that scientists believe we may attain with means as potent as genetics."

As a result of their survey, the authors believe that it is "both heartening to discover how much has been accomplished and humbling to realize how little we know." This would seem to reveal a desirable state of mind. They suggest that not only has the survey been worth while but that it would be well if a similar audit or stock taking could be made in other major branches of agricultural sciences, and they announce that such a plan is now projected in the Department. Doubtless it will be very useful.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Idaho Station], H. P. MAGNUSON (*Idaho Sta. Bul.* 221 (1937), pp. 9, 10).—The station has found the carotene content of pasture grasses to be well preserved during shipment by freezing in "dry ice", the samples having been ground on arrival at the main station in a Wiley mill with excess of the solid carbon dioxide. Notes are also given on some technical phases of potato alcohol production.

[Chemical and bacteriological investigations by the Massachusetts Station] (*Massachusetts Sta. Bul.* 339 (1937), pp. 23, 24, 32, 33, 34, 35).—Results are noted on the influence of bile and bile salts on *Aerobacter aerogenes*, by J. E. Fuller; lipolytic activity of Gram-negative intestinal bacteria, by Fuller and E. W. Harvey; the tolerance of the *coli-aerogenes* group for brilliant green and a study of the Eljkmán test, both by R. L. France; the action of the *coli-aerogenes* group on erythrosin, by France and Fuller; a new method for determining iodine in foodstuffs; hemicelluloses of tobacco stalks, by E. Bennett; and methods for determining the fate of certain constituents of vegetables during cooking, by M. E. Freeman.

[Chemical work of the Puerto Rico College Station], R. ARROYO (*Puerto Rico Col. Sta. Rpt.* 1935, pp. 12, 13, 52-54).—The report notes the progress of work on the bacterial production of *n*-butyric acid from sugarcane final molasses (more than 90 percent of the theoretical quantity of practically pure butyric acid having been obtained) and on the preparation of high-grade cellulose from sugarcane bagasse.

A bacterium that does a "Dr. Jekyll-Mr. Hyde" act, C. S. PEDERSON (*Farm Res. [New York State Sta.]*, 3 (1937), No. 4, pp. 2, 5, figs. 3).—The author presents a popular description of an organism (a *Leuconostoc*) growing in chains in laboratory media but in an encapsulated form in sugar solutions. In commercial sugar solutions a slimy product, largely a dextran, is formed. The organism is not only desirable but necessary, however, in the preparation of sauerkraut, in which it has been shown to be the cause of the primary fermentation. It is also used for the preparation of an acid alcoholic beverage from pineapple juice in the Philippines.

Vitamin P: Flavonols as vitamins, S. RUSZNYÁK and A. SZENT-GRÖRGYI (*Nature [London]*, 138 (1936), No. 3479, p. 27).—It is noted briefly that the authors in collaboration with L. Armentano and A. Bentsáth, have found ascorbic acid to be ineffective but vitamin C-rich extracts of Hungarian red pepper and lemon juice effective in the treatment of certain pathological conditions characterized by permeability or fragility of the capillary wall. Fractionation of the extracts resulted in the separation of the active substance in the fraction consisting of practically pure flavone or flavonol glycoside. Daily intravenous injections of 40 mg of this fraction restored normal capillary resistance in 2 weeks in patients suffering from permeability of the capillary walls, with spontaneous bleeding. The name vitamin P is proposed for the substance responsible for the action on vascular permeability.

Vitamin nature of flavones, A. BENTSÁTH, S. RUSZNYÁK, and A. SZENT-GYÖRGYI (*Nature [London]*, 138 (1936), No. 3497, p. 798, fig. 1).—Further evidence is given of the vitamin nature of the flavones tentatively termed vitamin P. Weight curves are shown of groups of guinea pigs receiving a scurvy-producing diet, with and without the addition of "citrin", the crystalline flavone fraction from lemon juice. In 17 animals receiving the diet without the addition, death occurred on an average of 28.5 days, with average weight declines from 359 to 242 g. In 21 animals receiving as a supplement 1 mg of citrin daily, none had died at the time, 34–38 days, when all of the first group were dead. The weight levels had fallen from an average initial weight of 365 to 342 g. All of the animals in both groups showed typical symptoms of scurvy in fragility of the bones, loosening of the teeth, and swelling of the joints, but the number of hemorrhages noted on autopsy was very much greater in the first group than in the one receiving citrin. "These results suggest that experimental scurvy, as commonly known, is a deficiency disease caused by the combined lack of vitamin C and P."

Chemical nature of citrin, V. BRUCKNER and A. SZENT-GYÖRGYI (*Nature [London]*, 138 (1936), No. 3503, p. 1057).—Further work on the crystalline flavone fraction of lemon juice capable of curing disorders of the capillary wall and termed citrin has shown it to consist of mixed crystals of two different dyes. One of these, hesperidin, m. p. 261° [C.], forms the major part of citrin, but the activity and color reactions of citrin are due to the other component, eriodictyol glucoside, a demethylated hesperidin. The active eriodictyol glucoside was not found in any considerable quantity in unripe oranges, while hesperidin was present in considerable amounts. The probability is suggested that eriodictyol glucoside is formed from hesperidin by demethylation during the ripening of the fruit.

From vitamin O to vitamin P, A. SZENT-GYÖRGYI (*Our Sci. [India]*, 5 (1936), No. 6, pp. 285, 286).—The author gives a brief historical review of the steps leading up to his isolation of vitamin C, ascorbic acid, and more recently of the flavone, vitamin P, responsible for inducing the reaction between peroxidase and ascorbic acid and capable of curing disorders of the capillary wall, such as hemorrhagic diathesis of the vascular type.

Ascorbic acid oxidase and the state of ascorbic acid in vegetable tissues, W. STONE (*Biochem. Jour.*, 31 (1937), No. 4, pp. 508–512).—Following a brief review of the literature reporting the presence of enzymes in certain plant materials capable of oxidizing ascorbic acid, data are reported on the apparent presence of such an enzyme in various fruit and vegetable juices.

Bananas, cabbage, carrots, cucumbers, vegetable marrow, potatoes, and string beans lost practically all of their indophenol-reducing power on mincing in the absence of metaphosphoric acid, but the property was restored with hydrogen sulfide in all the materials except cabbage. Under identical treatment cantaloup, lettuce, alfalfa, onions, green peas, spinach, and watermelon did not lose their indophenol-reducing property. The materials in the first group destroyed the reducing power of orange juice, while the others did not. Cucumber juice was mixed in varying proportions with orange juice containing 0.4 mg of ascorbic acid and incubated at 37° C. for 10 min., after which ascorbic acid determinations were made. The extent of destruction was shown to increase with increasing proportions of cucumber to orange juice, varying from 78 percent in the mixture of 5 volumes of orange juice to 0.5 of cucumber juice to 100 percent in mixtures of 2.5 volumes of orange juice to 5 of cucumber juice. The orange juice by itself lost no ascorbic acid by the treatment. In several tests with solutions of ascorbic acid instead of orange juice there was a destruc-

tion of about 27 percent under the conditions of the experiment with no added cucumber juice. This increased to 100 percent in mixtures of 5 cc of ascorbic acid containing 2.5 mg mixed with 5 cc of cucumber juice.

It is concluded that there is no dehydroascorbic acid in the intact vegetable tissue, but that this is formed when a cut or crushed vegetable containing the enzyme is exposed to air.

A supplementary note calls attention to the paper of Kertesz, Dearborn, and Mack (E. S. R., 77, p. 151) in which some of the vegetables found in the present study to contain no oxidase were reported to contain small amounts which act after a long time. To test this, lettuce, onions, fresh green peas, and spinach were tested before and after standing for 3 hr. at 37°. In no case were higher values obtained with the heated than the unheated juice and in three cases the values were actually lower. The enormous loss in spinach, 85 percent in the unheated and 91 percent in the heated juice, and the high loss in lettuce, 57 and 75 percent, respectively, are considered nonenzymic and attributed to the high iron and copper content of these vegetables. "This loss in spinach is of great importance because the mode of preparation of this vegetable for consumption is very conducive to the destruction of its excellent vitamin C content. In order to minimize this loss it should be served immediately after cooking."

The oxidation of l-ascorbic acid by plant enzymes, S. W. JOHNSON and S. S. ZILVA (*Biochem. Jour.*, 31 (1937), No. 3, pp. 438-453).—This paper reports a comparative study of the enzymic reversible oxidation of ascorbic acid by various plant food materials, as determined either on the juice or an enzyme prepared from the plant material. The juice was obtained by pressing between porcelain plates in a hand mill the material previously frozen at -20° C. If in a sample of the fresh juice adjusted to pH 7.6-8 a precipitate formed, the remainder of the juice was treated in the same way and readjusted to the original pH after removing the precipitate. The enzyme material was prepared according to the procedure of Szent-Györgyi involving precipitation by saturation with ammonium sulfate after removing impurities with barium acetate and excess of the latter with saturated ammonium sulfate, dissolving the precipitate from 100 cc of juice in 30 cc of $M/15$ KH_2PO_4 or $M/5$ sodium acetate (pH 6). Tests were made of the pH range of activity and sensitivity to cyanide, the aerobic nature of the enzyme activity as determined by comparison with methylene blue as hydrogen acceptor, the action of the enzyme on mono- and dihydricphenols and on ascorbic acid in the presence of catechol, and the peroxidase activity of both juice and enzymes.

Cabbage, cauliflower, cucumber, and vegetable marrow appeared to contain an enzyme which oxidizes l-ascorbic acid and d-glucosascorbic acid directly, but does not oxidize mono- or dihydricphenols. The apple and the potato did not contain such an enzyme but were able to hydrogenate ascorbic acid indirectly by previously oxidizing mono- and polyhydricphenols, if present, to their corresponding quinols, which in their turn oxidize ascorbic acid. The juices of the first group were able to oxidize catechol as well as ascorbic acid. When both were present the oxidation of catechol began only after the oxidation of ascorbic acid had been completed.

The oxidation of vitamin C, C. R. ADDINALL (*Merck Rpt.*, 46 (1937), No. 2, pp. 4-6; *abs. in Amer. Jour. Pharm.*, 109 (1937), No. 4, pp. 188-190).—A brief summary is given of the reducing properties of vitamin C, with particular reference to its chemical determination in foods and biological material.

The two steps in the oxidation of vitamin C are given as (1) ascorbic acid \rightleftharpoons dehydroascorbic acid and (2) dehydroascorbic acid \rightarrow l-threonic acid, oxalic

acid, and CO_2 . In the presence of atmospheric oxygen and in acid and neutral solution ascorbic acid is slowly oxidized. At $\text{pH} < 4$ oxidation stops at the first stage and can be reversed with H_2S . With increased alkalinity oxidation is greatly hastened and in the presence of sufficient oxygen ends at the second stage. Oxidation is hastened by minute traces of copper and oxidases and is retarded by salts, biological extracts, and erythrocytes.

Dehydroascorbic acid at $\text{pH} > 4$ undergoes spontaneous irreversible transformation into an acid with no antiscorbutic activity, the change being independent of air or oxidizing agents. Dehydroascorbic acid has high potency in vivo because of the reducing action of glutathione in the tissues converting it into ascorbic acid.

In crystalline form ascorbic acid is stable on exposure to air. In aqueous solution it gradually oxidizes. One-percent solutions are reported to have lost only 14 percent of their activity after a week's time. Neutralized solutions are more liable to oxidation, but solutions in sealed ampoules under an inert gas are stable indefinitely. In the human body the vitamin is rapidly carried to the tissues and maintained in the reduced active form until excreted in the urine.

"With due regard to interfering substances, and within the acid range indicated by the modification of Birch, Harris, and Ray, the Tillmans reaction gives a reasonable evaluation of the vitamin C content of biological material, but clinical findings must necessarily take into account the yet unsolved problems of metabolism and of the formation of physiologically inactive oxidation products with reducing properties. In the ultimate analysis, where it is not possible to isolate crystalline ascorbic acid from the test material, the biological assay is still the safest indication of the antiscorbutic action of material containing vitamin C."

A specific reaction for the qualitative and quantitative determination of ascorbic acid in serum, H. LUND and H. LIECK (*Nature [London]*, 137 (1936), No. 3471, p. 784).—The methylene blue reaction with ascorbic acid has been applied to its determination in very small amounts of blood serum. The examination is made with a stock solution consisting of KH_2PO_4 , 9 g, NaCl 2 g, with 0.004 percent methylene blue solution in 100 cc. To 0.9 cc serum, 0.1 cc of this solution is added. The mixture is exposed to the light of a 100-w Nitralamp, at a distance of 1 cm for 30 sec., and the intensity of the color is compared to that of a control. Fading of the intensity of color is distinct even with 0.1 mg percent. The color change is reversible in the dark.

The method is said to have no interference from glutamine, ergothionine, creatine, creatinine, urea, adenine, guanine, hypoxanthine, xanthine, uric acid, cystine, phenol, or hemoglobin. A negative reaction becomes strongly positive after the ingestion of 500 mg ascorbic acid. With modification it is thought to be suitable also for the determination of the ascorbic acid content of milk and urine.

Method for the determination of serum ascorbic acid with capillary blood [trans. title], A. ELMBY and T. K. WITT (*Klin. Wchnschr.*, 16 (1937), No. 21, pp. 746-748, figs. 5).—A special pipette has been devised to adapt the methylene blue titration method of Lund and Lieck noted above to microdeterminations requiring only from 0.1 to 0.2 cc of capillary blood from the ear lobe or fingertip. The instrument is described with diagram, the method is outlined briefly, and data obtained with the micromethod and the macromethod for comparison are reported. It is shown to be capable of detecting 0.2% of ascorbic acid dissolved in 1 cc and to be practicable for the determination of vitamin C saturation following test doses.

Estimation of ascorbic acid (vitamin C) by titration, IRENE GÁL (*Nature [London]*, 138 (1936), No. 3497, p. 799).—A slight modification of the Martini and Bonsignore methylene blue method (E. S. R., 73, p. 746) for determining ascorbic acid is described. This consists in the use of titanium trichloride in dilution of 5 in 1,000 to titrate any excess methylene blue remaining after the reaction with ascorbic acid. The titanium trichloride solution should always be freshly prepared and standardized against the standard methylene blue. To the metaphosphoric acid solution of the material to be examined for its ascorbic acid content, the methylene blue solution is added until after exposure to intense sunlight or to a 300-w lamp the color of the solution being titrated no longer changes. The solution is then titrated with titanium trichloride and the difference between the two values represents the ascorbic acid.

In the estimation of oxidized ascorbic acid the mercuric acetate technic of Emmerie (E. S. R., 72, p. 443) can be used if care is taken to remove hydrogen sulfide by carrying out the reaction in a stream of carbon dioxide.

Estimation of ascorbic acid (vitamin C) by titration, H. CHEFFEL and M. L. PIGEAUD (*Nature [London]*, 138 (1936), No. 3497, p. 799).—It is noted briefly that in determining ascorbic acid by the Harris and Ray modification of the Tillmans method the necessity for very rapid titration can be obviated by cooling the ascorbic acid solution to 0° C. and carrying out the titration at this temperature.

Metaphosphoric acid in the extraction and titration of vitamin C, R. R. MUSULIN and C. G. KING (*Jour. Biol. Chem.*, 116 (1936), No. 1, pp. 409-415).—"The titration procedure of Bessey and King [E. S. R., 71, p. 137] for the determination of vitamin C has been modified to include the presence of 2 percent metaphosphoric acid with acetic acid or trichloroacetic acid during extraction and titration. The modified procedure is advantageous for work with both plant and animal tissues.

"Metaphosphoric acid in approximately 2 percent concentration, as suggested by Fujita and Iwatake [E. S. R., 76, p. 155], serves to protect vitamin C in solution against atmospheric oxidation, even in the presence of added copper, and also exerts protective action against oxidation in the presence of trichloroacetic acid. The rate of reaction with 2,6-dichlorophenolindophenol is not appreciably affected by the presence of metaphosphoric acid."

Report on biological methods for vitamin B complexes, C. A. ELVREJEM (*Jour. Assoc. Off. Agr. Chem.*, 18 (1935), No. 3, pp. 354-356).—A report from the Wisconsin Experiment Station very briefly outlines a method capable of showing the vitamin B₁ potency of yeast samples. "It is recommended that the proposed method be studied in greater detail and collaboratively."

Soil and plant material analyses by rapid chemical methods, II, F. E. HANCE (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 [1937], No. 2, pp. 135-186, pls. 2, figs. 20; also *Hawaii. Sugar Planters' Sta., Agr. and Chem. Bul.* 51 (1937) pp. 135-186, pls. 2, figs. 20).—This paper supplements a previous article (E. S. R., 76, p. 438) describing rapid chemical methods of analysis "which are applicable to agricultural-chemical studies of soils, waters, plant materials, and mill byproducts." It also deals with "the application, preparation, use, and care of durable color standards for rapid colorimetric analyses."

A comparative study of certain presumptive media for testing raw waters, R. L. FRANCE (*Jour. Amer. Water Works Assoc.*, 28 (1936), No. 6, pp. 785-793; *abs. in Massachusetts Sta. Bul.* 339 (1937), p. 96).—This contribution from the Massachusetts Experiment Station records the results of an investigation in which it was shown in part that the use of lactose broth with confirmation of all positive presumptive tubes by inoculation into secondary tubes

of brilliant-green bile broth gave the highest total number of recoveries of the *coll-aerogenes* group from the raw waters tested. The results indicate that this method may prove the most satisfactory for testing raw polluted waters.

Speed and accuracy in determination of total nitrogen: The use of selenium and other catalysts, A. E. MURNEEK and P. H. HEINZE (*Missouri Sta. Res. Bul. 261 (1937), pp. 8*).—In the experiments here reported, the catalysts had little effect on the exactness of the determination of the nitrogen content of plant and soil samples, but they markedly increased the rate of digestion.

"The sample, varying from 0.5 to 10 g according to the nitrogen content, is placed in a 800-cc Kjeldahl flask, 30 cc of concentrated H_2SO_4 , containing 1 g of salicylic acid, is added and the contents thoroughly shaken and preferably allowed to stand overnight. Then 5 g $Na_2S_2O_8$ is added and the flask heated slowly for 5 to 10 min. Ten g of anhydrous Na_2SO_4 and the catalysts, consisting of 0.1 g selenium, 0.25 g $CuSO_4$, and 0.7 g HgO , are added, and the digestion continued till the total digestion time is approximately 1.5 times the clearing time for each sample. When cool, 300 cc of distilled water is poured into the flask, and enough concentrated $NaOH$ (1 g per cubic centimeter of H_2O), containing 1 g NaS for every 75 cc. is added to neutralize the acid and make the solution strongly alkaline. About 1.5 g of 20-mesh zinc is used to prevent bumping during the distillation.

"The use of the catalysts may be simplified by preparing a mixture of the three materials in the following proportion by weight: 10 of selenium, 25 of $CuSO_4$, and 70 of HgO . The $CuSO_4$ must be finely ground and the selenium and HgO thoroughly mixed with it. By using 1.05 g of this mixture the above mentioned amounts will be added."

Report on carbohydrates in plants: Study of the permanganate titration method for copper, J. T. SULLIVAN (*Jour. Assoc. Off. Agr. Chem., 18 (1935), No. 3, pp. 382-386*).—This report, contributed from the Indiana Experiment Station, takes up a study of the end point in the titration by permanganate of the copper reduced by sugar solutions.

"The addition of a drop of orthophenanthroline indicator to the copper solution before titration seems to eliminate the personal factor in the reading of the end point. The change in color is sharp and distinct and may easily be limited to a single drop of 0.05 N potassium permanganate. If the temperature is too high ($80^\circ C.$), the color of the indicator fades before the end point is reached, and in this case more indicator must be added. A warm solution is necessary for titration; 60° or above has always been recommended. It is most important in an accurate titration to have all the copper in solution. Though heat may assist this solution, it is safer to press out each particle with a rod, and it is unsafe to depend upon stirring alone. With careful manipulation the results with dextrose should agree with the electrolytic method."

The estimation of starch in plants with special reference to woody plants, J. T. SULLIVAN (*Jour. Assoc. Off. Agr. Chem., 18 (1935), No. 4, pp. 621-636, fig. 1*).—A procedure described in a contribution from the Indiana Experiment Station is based upon the extraction of the starch with slightly alkaline calcium chloride solution and its precipitation by iodine. The difficulties encountered in precipitating the starch iodide in the presence of calcium chloride are avoided by removing the calcium chloride and substituting ammonium sulfate as the flocculating agent. The double precipitation necessary tends to purify the starch precipitate.

"The conditions that must be observed in order to obtain the maximum yield of starch by one extraction involve the concentration of the calcium

chloride, the duration of the boiling, and the degree of fineness to which the sample is ground. When the proper conditions are used, the yield of starch obtained by one extraction agrees with that obtained by successive extractions under less drastic conditions. This indicates that all the starch has been brought into solution.

"Recovery of potato starch alone or when added to plant material indicates that no starch is lost during the process. The quantities of starch obtained by this method represent the true starch values more closely than those obtained by enzymatic methods."

Report on gums in foods, L. J. CROSS (*Jour. Assoc. Off. Agr. Chem.*, 18 (1935), No. 3, pp. 432, 433).—A report contributed from the New York State Experiment Station presents the results of a trial by 10 collaborators of a method for detecting gums in cream cheese samples. In samples containing, respectively, about 0.1 percent, about 0.05 percent, and no added gum or agar, 9 analysts found the gum present in the first sample, 10 in the second sample, and 8 out of the 10 found gum to be absent from the third sample.

Report on refractometric determination of oil in seeds, T. H. HOPPER (*Jour. Assoc. Off. Agr. Chem.*, 18 (1935), No. 3, pp. 433, 434).—A report contributed from the North Dakota Experiment Station notes that "the refractive index (25° C.) of oil from commercial flaxseed has varied from 1.47550 to 1.47975 during recent seasons. With this wide variation some question arises as to the value of the method for the estimation of the oil in the seed, as the method assumes that the refractive index is fairly constant."

The chemical analysis of butter for moisture, salt, curd, and fat, L. C. THOMSEN ET AL. (*Jour. Dairy Sci.*, 20 (1937), No. 6, pp. 351-357).—This is a report by the subcommittee on the chemical analysis of butter of the American Dairy Science Association, superseding a previous report of this subcommittee (*E. S. R.*, 65, p. 110).

Development of methods for the estimation of mold in cream or butter, J. D. WILDMAN (*Jour. Assoc. Off. Agr. Chem.*, 20 (1937), No. 1, pp. 93-100, figs. 3).—This article from the U. S. D. A. Food and Drug Administration describes a microscopic method for estimating the amount of vegetable mold in butter and a rapid macroscopic method (methylene blue-borax test) for detecting and estimating the amount of mold in cream.

Report on fat in feeding stuffs, L. S. WALKER (*Jour. Assoc. Off. Agr. Chem.*, 18 (1935), No. 3, pp. 349-351).—This contribution from the Vermont Experiment Station compares as to consistency and accuracy of results a short extraction method involving the use of a Goldfish extractor (3 or 4 hr.) with the Official (16 hr.) extraction. The author makes no recommendation on this subject, but presents a record of what this apparatus will do, stating that "any chemist who desires a quick accurate method for the determination of crude fat (ether extract) in feeding stuffs might consider it."

A simple method for determining the lactic acid in silage [trans. title], O. FINE (*Biedermanns Zentbl., Abt. B. Tierernähr.*, 9 (1937), No. 2, pp. 178-183; *Eng. abs.*, p. 183).—A method based on the conversion of lactic acid in silage extracts into acetic acid by controlled oxidation with chromic and sulfuric acids and determining the acetic acid content by distillation is described.

Report on santonin, H. J. FISHER (*Jour. Assoc. Off. Agr. Chem.*, 18 (1935), No. 4, pp. 526-532).—This contribution from the Connecticut [New Haven] Experiment Station deals with a method for determining santonin by converting it into a dinitrophenylhydrazone, which was found to be quantitatively insoluble in the dilute alcohol (1:2) used for washing the precipitate. Procedures based upon this principle were found capable of somewhat more accurate results

than the methods now in use when applied to pure santonin, but it was less satisfactory with mixtures, and for these it is recommended that the present tentative method be retained.

Report on less common elements in plants, J. S. MCHARGUE (*Jour Assoc. Off. Agr. Chem.*, 18 (1935), No. 3, pp. 377, 378).—Some results obtained in the use of a combustion method for determining iodine in crops and food materials at the Kentucky Experiment Station are stated.

AGRICULTURAL METEOROLOGY

Bibliography of meteorological literature (*Roy. Met. Soc. [London], Bibliog. Met. Lit.*, 4 (1936), No. 1, pp. [2]–[53]).—The preface of this bibliography traces the development from its beginning in 1917 as a feature of the *Quarterly Journal of the Royal Meteorological Society* (E. S. R., 48, p. 614).

"The arrangement used until the end of 1935 was a modification of that adopted for the 'International Catalogue of Scientific Literature', issued by the Royal Society from 1900 to 1916. . . . In September 1935 the International Meteorological Conference at Warsaw adopted and recommended for international use a new classification forming part of the 'Universal Decimal Classification.' This classification was adopted for use in the libraries of the Royal Meteorological Society and the Meteorological Office from January 1, 1936, and will be used in the bibliography for literature received since that date.

"The rapid increase in the volume of meteorological literature has made it necessary to limit the bibliography to the more important works and also to contract still further the titles of periodicals."

Monthly Weather Review [March–April 1937], (*U. S. Mo. Weather Rev.*, 65 (1937), Nos. 3, pp. 97–133, pls. 11, figs. 15; 4, pp. 135–174, pls. 9, figs. 7).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 3.—Total Solar and Sky Radiation on Mount Washington, N. H., by B. Haurwitz (pp. 97–99); Glaze Storm of March 17–19, 1936, in Pennsylvania and New York, by A. A. Downs (pp. 100, 101); Absorption of Radiation by Water Vapor as Determined by Hettner and by Weber and Randall, by H. Wexler (pp. 102–104); and Aircraft Icing Zones on the Oakland-Cheyenne Airway, by J. A. Riley (pp. 104–108).

No. 4.—On the Relation Between Rainfall and Stream Flow, III, by R. T. Zoch (pp. 135–147) (see p. 747); Preliminary Report on a Study of Atmospheric Chlorides, by W. C. Jacobs (pp. 147–151) (see p. 747); and Duststorms of January–April 1937 in the United States, by R. J. Martin (pp. 151, 152).

Climatic cycles, D. BRUNT (*Geogr. Jour.*, 89 (1937), No. 3, pp. 214–238, figs. 9).—From a study of various long-time records of temperature and rainfall at a number of places in different parts of the world, considered in connection with sunspot cycles, tree rings, lake levels, clay varves, and other sources of information, the author states that "none of the cycles found occur with such great amplitudes that we can assert that they might not be due to a chance distribution of the observations, and not to truly periodic variations. It is shown that even if some of the cycles found are real physical cycles, they can only account for a small part of the variability of the meteorological phenomena; so small a part indeed that it is of little importance whether the so-called cycles are real or not."

Recent changes of climate and vegetation in southern New England and adjacent New York, H. M. RACP (*Jour. Arnold Arboretum*, 18 (1937), No. 2, pp. 79-117).—The author presents climatic and other evidence tending to show "changes in general living conditions in New England and adjacent New York during the past 3,000 yr., with effects lasting into more recent time." From such evidence the author infers that "a warmer and drier climate has occurred in New England within the past 3,000 yr. The trend since the peak of the warm dry era has been in general toward the cooler and more moist, but probably with minor variations in the opposite direction. There is evidence, further, that the warm dry climate was so recent that the effects of it are still with us in the form of disrupted ranges for southern animals, plants, and forest types. Judging by various estimates related to the rate of subsidence and of peat deposition at the shore, it is thought that the warm water fauna was still abundant on our coast about 1,000 yr. ago, a figure which places the warm period in general coincidence with similar eras in the Middle Western States, in northern Europe, and in Greenland."

On the relation between rainfall and stream flow, III, R. T. ZACH (*U. S. Mo. Weather Rev.*, 65 (1937), No. 4, pp. 135-147, figs. 3).—Continuing earlier work (E. S. R., 73, p. 12; 75, p. 590), this is primarily a mathematical study of rainfall and stream-flow relationships, with special reference to rate of rainfall, condition of soil, velocity of the water, and evaporation.

Western Interstate Snow-Survey Conference (*Amcr. Geophys. Union Trans.*, 17 (1936), pt. 2, pp. 529-562, figs. 12).—Reports and papers presented at the conference at Pasadena, Calif., January 31, 1936, are given as follows: Status of Coordination and Standardization of Snow-Surveying, by J. C. Marr (pp. 530-533); Precipitation-Surveys for Anticipating Water-Supplies, by H. K. Burton and J. C. Alter (pp. 533, 534); The Effect of Soil-Absorption on Snow-Survey Forecasting of Stream-Flow, by H. P. Boardman (pp. 534-537); Calculation of Normals for Use with Snow-Survey Data, by C. H. Lee (pp. 537-539); Lamoille Creek Basin Normals—a Case in Which Extension of Normals by Comparison With Precipitation-Data Proved More Valuable Than by Comparison With Another Stream, by C. Elges (pp. 539-542); Extension of Normals by Precipitation-Data and by Comparison With Another Stream, by G. L. Parker (pp. 542, 543); Soil-Absorption and Its Effect on Stream-Flow Forecasts in Utah, by G. D. Clyde (pp. 543-545); The Adirondack Snow-Survey, by E. S. Cullings (pp. 545-548); Instructions to Observers (pp. 548-550); Improvement in Snow-Survey Apparatus, by J. E. Church (pp. 550-557); Questionnaire and Answers on Snow-Survey Equipment and Methods, by J. E. Jones (pp. 557-562); and Historical and Administrative, by J. E. Church (p. 562).

Microclimatic character of the warm air layer on the soil, I-III [trans. title], R. GEIGER (*Met. Ztschr. [Braunschweig]*, 53 (1936), No. 10, pp. 357-360, figs. 2; 54 (1937), Nos. 4, pp. 133-138, figs. 3; 8, pp. 278-284, figs. 5).—In a study of the heat relations of the air layers within 2 m of the soil, using a special form of electric thermometer under different diurnal and weather conditions, especially those prevailing on warm, sunny days and at different times of the day, it was found that temperatures were from 6° to 36° C. higher at midday near the surface of grass-covered soil than in an ordinary thermometer shelter. At night it was from 2° to 6° colder. The marked influence of wind on temperature variations was confirmed.

Preliminary report on a study of atmospheric chlorides, W. C. JACOBS (*U. S. Mo. Weather Rev.*, 65 (1937), No. 4, pp. 147-151, figs. 4).—Observations and analyses are reported which indicate "that there is considerable chloride

present in the air and that the supply is continually being replenished from the sea. It is indicated, further, that a large proportion of the particles must be of such small size that they are capable of remaining suspended in the air. Except for an excess of chloride, which might occur with the presence of extremely large droplets or sea spray resulting from high onshore winds, it is believed that the droplets of sea water are true colloids and, as such, even without evaporation, may be considered as semipermanent in the atmosphere. That is, they may remain suspended permanently unless removed through condensation and precipitation."

Climatological data for the United States by sections, [1936] (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 23 (1936), No. 13, pp. [261], pls. 5, figs. 27).—Summaries are given of climatological data for each month of 1936 and for the year as a whole for each State.

Meteorological summary for 1935 at Fairbanks, Alaska, R. L. FROST (*Alaska Sta. Bul.* 5 [1936], pp. 3-6).—It is stated that the winter of 1934-35 at Fairbanks was unusually mild, the lowest temperature being only -42° F. Snowfall during the first few months of winter was very light, but the total for the year was 116.2 in., more than twice the normal. The summer months were generally cool and cloudy. The highest temperature recorded in 1935 was 84° on July 8, and the lowest was -59° on December 7. The average temperature for the year was 23.8° , 2.2° below normal. The total precipitation for the year was 17.48 in., 5.99 in. above normal. There were 83 clear days, 92 partly cloudy, and 190 cloudy days. One hundred percent sunshine was recorded on 58 days, and the days entirely without sunshine totaled 81. The last killing frost in spring for tender plants was May 24, the last for hardy plants May 14. The first killing frost in fall for tender plants was August 22, for hardy plants September 9.

[Meteorological summary for 1936] (*Alaska Sta. Bul.* 6 [1937], pp. 3-5, 6, 39).—The summer season of 1936 in the Tanana Valley up to August 18 was very dry. The average temperature from May to August was 4.5° F. above normal. The high temperature and dry weather hastened maturity of grain and delayed growth of potatoes. The "growing season for tender plants extended from May 12 to September 8, a total of 119 days. For hardy plants, the growing season lasted from May 10 to September 8."

Meteorological tables, H. M. WILLS and A. E. WHITE (*Mich. State Bd. Agr., Ann. Rpt. Sec.*, 75 (1936), pp. 219-232).—Data corresponding to those previously noted (*E. S. R.*, 75, p. 590) are reported for the year ended June 30, 1936.

SOILS—FERTILIZERS

[Soil and fertilizer investigations by the Idaho Station] (*Idaho Sta. Bul.* 221 (1937), pp. 8, 9, 46, 47).—Work is reported on the availability of phosphorus in Idaho soils and fertilizer experiments with "slick" soils, both by H. P. Magnuson, and negative results with raw rock phosphate, by J. Toevs.

[Soil and fertilizer work of the Kentucky Station] (*Kentucky Sta. Rpt.* 1936, pt. 1, pp. 22, 23, 40-43, 55).—The station reports work on the iodine content of plant materials, soils, and fertilizers; effect of limestone on availability of rock phosphate; comparison of phosphates under field and greenhouse conditions; effect of manure in a cropping rotation; a new method for determining soil moisture; and soil management studies.

[Soil research by the Massachusetts Station] (*Massachusetts Sta. Bul.* 339 (1937), pp. 10, 11, 12, 13, 14, 32, 35, 46).—Brief reports are included on magnesium requirements of plants, by W. S. Eisenmenger and K. J. Kucinski; the comparative nutritive effects of copper and zinc, by H. R. DeRose, Eisen-

menger, and W. S. Ritchie; distribution of nitrogen in soils mixed with different plant tissues and allowed to react for 2 mo., by Eisenmenger; experimentation with artificial manure, including analyses, by Kucinski and Eisenmenger; the water-supplying power of soils, by L. H. Jones; and a survey as to the extent of soil erosion in Massachusetts, by D. Rozman.

[Soil and fertilizer research by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1936], pp. 26-28, 30, 31).—The work here reported includes experimental studies of optimum soil nitrate levels, effect of day length and acidity on the assimilation of nitrate and ammonia nitrogen, the effect of crops on soil acidity, the effect of magnesian liming materials on the calcium in forage plants, basicity of fertilizer ingredients, and availability of the phosphates in calcined phosphates and calcium metaphosphate.

[Soil Survey Reports, 1930 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils* [Soil Survey Rpts.], Ser. 1930, Nos. 43, pp. 80, figs. 4, maps 2; 44, pp. 36, figs. 2, map 1; 45, pp. 59, pl. 1, figs. 2, map 1; 46, pp. 29, pls. 2, figs. 3, map 1).—The four surveys noted were prepared in cooperation with other agencies, No. 43 the Vermont Experiment Station and Commission on Country Life, Nos. 44 and 45 the Indiana Station, and No. 46 the Michigan Station and Department of Conservation.

No. 43. *Soil survey (reconnaissance) of Vermont*, W. J. Latimer et al.—Vermont possesses a land area of 5,839,360 acres, of which the outstanding physiographic features are the Green Mountains and other ranges and isolated peaks, a rather high plateau, and the broad, low Champlain Valley of the northwestern part of the State.

The present reconnaissance report lists 41 series inclusive of 58 types and numerous slightly variant phases of these types. The total area is so evenly distributed among the many types that no one type covers a noteworthy percentage of the total area of the State, Berkshire stony loam leading with 6.9 percent. Rough stony land covers 22.1 percent and is devoted mainly to forestry.

No. 44. *Soil survey of Rush County, Indiana*, C. S. Simmons et al.—Rush County covers 261,760 acres somewhat southeast of the center of Indiana. Drainage is to the Ohio River, mostly by way of the East Fork White River, the White River, and the Wabash River.

The report lists 19 series divided into 22 types. Brookston silty clay loam, a highly productive soil, is the most extensive, occupying 28.5 percent of the area surveyed. Russell silt loam covers 17.7, Miami silt loam 13.3, and Crosby silt loam 12.4 percent.

No. 45. *Soil survey of Dubois County, Indiana*, C. S. Simmons et al.—Dubois County contains 273,280 acres of generally well-drained, for the most part gently rolling lands in the southwestern part of Indiana.

The report lists 23 series, 27 types. Zanesville silt loam covers 50.3 percent of the area examined and Holly silt loam 15.4 percent. The section on management was written by A. T. Wiancko and S. D. Conner.

No. 46. *Soil survey of Iron County, Michigan*, Z. C. Foster et al.—Iron County possesses a land area of 751,360 acres in the western part of the Upper Peninsula of the State and is, in general, "moderately hilly."

The soils of this county are listed as 26 series, inclusive of 31 types. The more extensive of these soils are Iron River silt loam and loam, 17 and 12.8 percent, respectively, Hiawatha fine sandy loam 10.1 percent, and carbondale muck 8.3 percent of the county.

[Soil Survey Reports, 1932 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils* [Soil Survey Rpts.], Ser. 1932, Nos. 17, pp. 40, figs. 2, map 1; 18, pp. 36, pls. 2,

figs. 2, map 1; 19, pp. 38, figs. 2, map 1).—The three surveys noted in these reports were carried out with the cooperation of the North Carolina Department of Agriculture and Experiment Station, the South Carolina Station, and the Oklahoma Station, respectively.

No. 17. *Soil survey of Brunswick County, North Carolina*, S. O. Perkins and E. F. Goldston.—Brunswick County, southeastern North Carolina, is an area of 546,500 acres of Atlantic Coastal Plain "flatwoods", of which "only slightly more than 6 percent of the total area is cleared and under cultivation", mainly because of "inadequate drainage and large areas of poor soils." The county is, in general, flat to undulating, and "probably not more than 30 percent of the land is naturally well drained."

There were found in Brunswick County 19 series of soils, including 29 types, but the most extensive of these classified types, Leon fine sand, covers only 9.1 percent of the county. Unclassified lands take up nearly one-fourth of the total area. Of the total area 24.4 percent consists of swamp, coastal beach, meadow, peat, peaty muck, and tidal marsh.

No. 18. *Soil survey of Abbeville County, South Carolina*, F. R. Lesh et al.—Abbeville County, northwestern South Carolina, is an area of 326,400 acres which "ranges from undulating and rolling to strongly rolling, steep, and broken." The county includes also a rather large flatwoods section. Drainage ranges from fair, with poor subsoil drainage, to excessive and erosive.

Of the 11 series and 16 types found in Abbeville County, Cecil clay loam is the most extensive, covering 33.4 percent of the county, and its nonagricultural broken and stony phases take up 11.8 percent additional. Cecil sandy loam, of which 12.2 percent out of a total of 15.3 percent is a mixed phase, is second in areal extent. Under the head of "miscellaneous land types" are listed a total of 27.2 percent either entirely nonagricultural or very poor.

No. 19. *Soil survey of Mayes County, Oklahoma*, M. H. Layton and O. H. Brensing.—Mayes County, northeastern Oklahoma, occupies 432,640 acres of lands lying partly in the Ozark region and partly in the prairies. Drainage is provided by the Neosho River and numerous tributaries.

The soils of this county form 16 series of 23 types. Bates very fine sandy loam constitutes 15.5 percent of the soil area examined, Parsons silt loam following with 14.9 percent and Okoee stony loam with 13.9 percent. Rough stony land totals 4.4 percent.

Soil survey of Indiana County, Pennsylvania, R. T. A. BURKE ET AL. (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.], Ser. 1931, No. 27, pp. 52, figs. 2, map 1*).—Indiana County occupies an area of 530,560 acres in west-central Pennsylvania. The lands of this county consist in general of "rather smooth rolling and hilly country." Drainage, provided by the Allegheny and Susquehanna River systems, is "matured and dendritic" and is quite generally very good.

The soils mapped in the county are included in 17 series, consisting of 34 soil types and 12 phases. The more important types are Ernest silt loam and Gilpin gravelly silt loam, each 11.4 percent of the total area surveyed.

This survey was carried out with the cooperation of the Pennsylvania Experiment Station.

Soil properties determining the botanical composition of pastures in West Virginia, R. R. ROBINSON (*Jour. Agr. Res. [U. S.], 54 (1937), No. 12, pp. 877-897, figs. 5*).—In a cooperative investigation carried out by the U. S. D. A. Bureau of Plant Industry and the West Virginia Experiment Station, soils belonging mostly to the Hagerstown and Dekalb series were analyzed for pH, available phosphate, total nitrogen, total exchange capacity, total exchange-

able bases, exchangeable potassium, and in some cases exchangeable calcium, magnesium, and soda. The percentage base saturation was calculated from the values for total exchangeable bases and total exchange capacity. Soil samples stored air-dry for a period of 1 yr. showed marked increases in available phosphate.

"A straight-line relationship was found to exist between the total nitrogen content and the total exchange capacity of these soils, the coefficient of correlation being 0.804 (n is 119, and the probable minimum correlation is 0.74). This high correlation emphasizes the importance of the organic exchange complex and is especially significant since the texture of the soils varied from sandy loams to silty clay loams. In general, the percentage base saturation of the soils studied is closely associated with the pH value, the coefficient of correlation for the entire group being 0.922 (n is 117, and the probable minimum correlation is 0.9). In the Dekalb soils, however, it was found that with a high ratio of organic to inorganic exchange complex, the percentage base-saturation values at a given pH value were relatively high, showing that the acids of the organic exchange complex are stronger than those of the inorganic.

"A comparison of the nitrogen content of the 0- to 3- and the 3- to 6-in. layers of Dekalb soils that have been in permanent pasture about 20 to 50 yr. shows that the 0- to 3-in. layer is 85 percent higher in available phosphate and 65 percent higher in total nitrogen than the 3- to 6-in. layer. The data indicate that approximately 1,000 lb. per acre of nitrogen have been accumulated during this period.

"A comparison of samples from the same pastures shows that, in general, soils supporting Kentucky bluegrass are higher in pH, percentage base saturation, total exchangeable bases, available phosphate, total nitrogen, and exchangeable potassium than soils supporting *Danthonia*. A statistical analysis of all samples, however, shows that the primary chemical properties limiting the percentage of Kentucky bluegrass and white clover in the pastures studied are percentage base saturation and available phosphorus. On shaly loam soils moisture appears to be limiting to the extent that Kentucky bluegrass and white clover may not be able to maintain a stand, although the chemical properties of the soil indicate that conditions are favorable for these species. Moreover, the soils supporting bentgrass are in a higher state of fertility than those supporting *Danthonia*, and consequently when Kentucky bluegrass is competing with bentgrass rather than with *Danthonia*, the available plant food must be greater in order to support a good stand of Kentucky bluegrass. . . .

"In the Hagerstown soils there is a high correlation between the percentage of Kentucky bluegrass plus white clover in the pasture and the amount of available phosphate in the soil. The index of correlation for this relationship is 0.901 (n is 17, and the probable minimum correlation is 0.79). The studies on the Dekalb soils show that percentage base saturation is a much better measure of the effect of soil acidity on the plant than is pH value, the index of correlation with the percentage of Kentucky bluegrass plus white clover being 0.800 for pH and 0.945 for percentage base saturation. The probable minimum correlations are 0.60 for pH and 0.88 for percentage base saturation. The data indicate that the relationship between the chemical properties of the soil and the amounts of Kentucky bluegrass and white clover is closer within a soil series than among different series.

"In general, 60-percent base saturation, corresponding to about pH 5.5 for the soils studied, 0.145 percent of total nitrogen, and 0.2 milligram equivalents

of exchangeable potassium per 100 g of soil appear adequate for maximum percentages of Kentucky bluegrass and white clover on these soils, if other factors are not limiting. On the basis of values obtained shortly after the samples were collected, 18 p. p. m. of available phosphate appear adequate for a good stand of Kentucky bluegrass and white clover, if other conditions are not limiting. On the basis of determinations made 1 yr. later, 24 p. p. m. are necessary. It should be recognized, of course, that the minimum values for percentage base saturation, total nitrogen, and available phosphate necessary for the maintenance of a high percentage of Kentucky bluegrass and white clover in permanent pastures are lower than the values necessary for the production of maximum yields."

Soil organic matter investigations upon Coastal Plain soils, J. B. HESTER and F. A. SHELTON (*Virginia Truck Sta. Bul. 94 (1937), pp. 1395-1428, figs. 9*).—The authors analyzed certain of the truck gardening soils in the eastern part of the State to determine the content of organic matter (carbon $\times 1.724$) and the nitrogen content of the surface soil and subsoil.

"The importance of humus in the soil to the availability of phosphates added to the soil has been determined in field and greenhouse experiments. Further, the growth of green manure crops upon soils that have been highly fertilized in the past absorbs and makes available to vegetable crops some of the unavailable phosphates.

"During 3 yr. of a rotation of potatoes followed by sorghum or soybeans, more than 20,000 lb. per acre of top growth was realized from the green manure crops. During this period the organic-matter content of this soil was increased 6,000 lb. per acre. Through the use of a system of cover crops the yield of potatoes was increased as much as 92 percent.

"The data given indicate the advantage of using nitrogen with nonleguminous crops. . . . With potatoes, both legume and nonlegume with mineral nitrogen are very satisfactory for increasing crop yield. Many other materials like manure, pine needles, and peat may be used to increase the organic-matter content of the soil, but they do not conserve the plant nutrients as do growing cover crops."

Rotations for soil improvement are suggested.

Soils in relation to fruit growing in New York.—XI, The organic-matter content of New York orchard soils in relation to orchard performance, R. W. CUMMINGS (*[New York] Cornell Sta. Bul. 672 (1937), pp. 26, figs. 3*).—In continuation of the work previously noted in this series (E. S. R., 77, p. 308), the carbon and the nitrogen content were determined on 96 surface soils and 31 subsoils in Wayne, Orleans, Monroe, and Columbia Counties. The nitrogen content was determined also on 65 additional surface soils selected from pits dug for rooting studies in Baldwin apple orchards in Wayne and Orleans Counties.

"The carbon content ranged from 0.75 to 3.95 percent in surface soils and from 0.03 to 1.35 percent in subsoils. Correspondingly, the organic-matter content varied from 1.29 to 6.81 percent in surface soils and from 0.05 to 2.33 percent in subsoils. The nitrogen content ranged from 0.056 to 0.319 percent in surface soils and from 0.007 to 0.072 percent in subsoils. The mean carbon:nitrogen ratio for 96 surface soils was 12.74 ± 0.08 with a range of 10.4 to 17.9, and for 31 subsoils it was 8.25 ± 1.33 with a range of 2 to 38.6. The mean carbon:nitrogen ratio, and also the mean percentages of carbon and nitrogen, for the Columbia County soils were slightly lower than those for the lake shore counties. This may or may not be significant.

"In Wayne and Orleans Counties the organic-matter content of surface soils shows no significant correlation with the available yield data, even within soil types or within groups of similar soils. Although fewer comparisons are possible, trunk circumference shows no consistent relation to organic-matter content of the soil in the orchards studied in Columbia County."

It is concluded that the determination of total organic carbon, nitrogen, or organic-matter content of a surface soil in itself has little or no prediction value as to the behavior of apple trees planted on that soil.

Forest lysimeter studies under red pine, H. A. LUNT (*Connecticut [New Haven] Sta. Bul. 394 (1937), pp. 217-268, figs. 12*).—Six tank-type lysimeters and 12 of the pan type (an improved design) were maintained in a red pine plantation 3 and 2 yrs., respectively, "for the purpose of determining the kind and amount of materials which leach out of (1) the forest floor (herein referred to as litter), (2) the upper 4 in. of mineral soil, and (3) the litter and soil together in their natural position." Nitrates, conductivity, and reaction were determined following each significant rainfall. The other constituents were determined on composite aliquots three times a year.

In the course of the year, natural precipitation in a red pine plantation caused the removal from the litter of from 7 to 81 lb. of nitrogen per acre, 29 to 53 of calcium, 14 to 81 of potassium, 18 to 35 lb. of sulfur, lesser amounts of magnesium, and small amounts of iron, phosphorus, and silica. "The larger amount in each instance refers to the maximum obtained in the tank lysimeters where root competition was eliminated. The smaller figure represents the minimum amount from the pan lysimeters with normal root competition." The mean annual amounts of the four main constituents leached from the pan-litter lysimeters were nitrogen 16 lb., calcium 30, potassium 15, and sulfur 18 lb. From the analysis of freshly fallen pine needles, it is estimated that the amount of material deposited on the soil each year in a plantation of the age of this one approximates from 55 to 60 lb. of nitrogen, 30 of calcium, and 15 lb. of potassium, "to which must be added the amounts brought down by rainfall and that resulting from decomposing roots and animal remains. It is impossible to strike a balance . . . with any degree of accuracy, but the figures given indicate that there is a fairly close balance between deposition and removal.

"In the case of the tank lysimeters the amounts of nitrogen, calcium, and potassium which came from the litter constituted a significant portion of the total amount present in the litter as determined by analysis.

"Leachate from the bare soil yielded during the course of a year from 1.5 to 40 lb. of nitrogen, from 9 to 47 . . . of calcium, 3 to 19 of potassium, 8 to 20 lb. of sulfur, and small amounts of other materials. While these amounts were, on the whole, less than that which came from the litter, the concentration in milligrams per liter was as great or greater than that from the litter. Excepting nitrogen obtained during the first year in the tank lysimeters, the amount of constituents obtained from the soil-and-litter lysimeters was, in general, no greater than that from the litter alone, and the concentration was not greatly different. Such data indicate that the soil absorbed or fixed much of the material coming from the litter; otherwise the amounts from the soil and litter would equal the sum of that from the litter and the bare soil. The greatest amount of nitrogen was obtained in the second period, i. e., between July 15 and November 20 . . . This was not true of calcium, potassium, or any other constituent for which analysis was made."

It is concluded in part that, under natural forest conditions, especially those of an evergreen forest (the presence of roots which constantly draw upon the moisture and plant nutrients liberated by the decomposing litter), losses by percolation are practically nil. "A forest soil may be likened to an agricultural soil which is kept in crop continuously—pasture or alfalfa, for example—but with the added advantage of lessened evaporation because of the shade and retarded wind movement."

Variation in the nitrogen content of irrigation water carrying dissolved nitrogen fertilizer, R. J. BORDEN and K. H. BERG (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 2, pp. 91-97, figs. 4).—Experiments showing considerable variations in the nitrogen content of water carrying dissolved sodium nitrate to sugarcane are reported. Practical suggestions are made for better control and approved technic to avoid uneven distribution of fertilizer material and spotty cane growth.

Effect of superphosphates in conserving nitrogen in cow manure A. B. MINGLEY and V. L. WILSER (*Vermont Sta. Bul.* 419 (1937), pp. 23, fig. 1).—Superphosphate of high calcium sulfate content was found more effective in conserving ammoniacal nitrogen than that containing relatively little of the sulfate.

"Gypsum (calcium sulfate), when used alone, is of little service in conserving ammoniacal nitrogen, but works well when added to a phosphate. Its calcium is then partially removed in the precipitation of tricalcium phosphate, leaving an equivalent amount of sulfuric acid to form a stable compound—ammonium sulfate. While phosphorus solubility is greatly reduced by the formation of tricalcium phosphate, which is precipitated in a very finely divided form and in the presence of decaying organic matter, its availability is not materially reduced. On the other hand, it is quite possible that it may become even more available to plant uses in this condition since it is less easily fixed into nonavailable forms by the soil."

It is further pointed out that the use of superphosphate to conserve the ammoniacal nitrogen of manures has a special value in Vermont in that most of the soils of the State need additional supplies of available phosphate. Usage in the stable is advocated both for this reason and for its value as an absorbent and antiseptic.

Overliming injury in relation to tannin-containing materials, A. R. MINGLEY and D. E. DUNKLEE (*Vermont Sta. Bul.* 420 (1937), pp. 28, figs. 2).—This bulletin reports a further investigation into the probable nature and cause of the overliming injury already studied by the station (*E. S. R.*, 68, p. 598).

Overliming injury in relation to tannin-containing materials, A. R. definitely toxic effect which injures, and frequently kills, seedlings before they have had time to exhaust even the food reserves of the seed. It is not relieved by supplying available nutrients.

Overliming injury could only be produced by heavy applications of lime to very acid soils. Like treatment of neutral or basic soils did not engender the toxicity in question. Podzolized soils, "especially the severely leached A horizons", produced an especially severe toxicity. Also, "normal soils relatively high in organic matter may be made to produce similar injury if, before liming, they are treated with acid to remove their bases, in a way comparable to the processes of podzolization. . . . The toxin is hard to destroy, but it is possible to get rid of it by completely removing the organic matter. . . ."

"Many plant tissues and tree barks, made acid in a manner equivalent to the process of podzolization, caused typical overliming injury when used as media on which to grow flax seedlings. Only tannin-bearing materials produced this trouble, the barks of hemlock, spruce, pine, and other plants normally growing on podzolized soils being especially harmful." The tannin content of the plant materials active in producing overliming injury was shown to be usually a catechol tannin rather than a pyrogallol tannin. "The chemical structure of the natural bodies causing overliming injury is not known. They seem to be phenolic resinous substances related to tannins." It is noted that synthetically prepared phenolic resins have been "produced and made to cause typical overliming injury."

Minor elements and crop fertilization, R. C. COLLISON (*New York State Sta. Circ. 168 (1937), pp. 13*).—Following a brief historical outline, the author limits the discussion mainly to boron, manganese, copper, and zinc and to physical and chemical characteristics of soils likely to be associated with deficiencies in one or more of these four elements.

"In attempting . . . to predict, if possible, the particular soils in which these minor elements would most likely be deficient, one would naturally look for soils with the following characteristics: (1) Soils high in silica and low in silicate minerals, in other words, the sandy soils of water-laid origin, low in organic matter; (2) soils originally low in lime or those from which most of the lime has been leached, in other words, soils with an acid profile throughout; (3) soils showing little or no compaction throughout the profile, in other words, well-drained soils in which unobstructed leaching has taken place over long periods of time. These characteristics would be accentuated in regions of high rainfall."

The author points out that stimulation of plant growth may be produced by small additions of the minor elements even where actual deficiencies, as indicated in the plants by physiological disturbances, do not exist.

Selenium in plants in relation to its occurrence in soils, J. T. MILLER and H. G. BYRES (*Jour. Agr. Res. [U. S.], 55 (1937), No. 1, pp. 59-68, figs. 5*).—In a contribution from the U. S. D. A. Bureau of Chemistry and Soils, the authors report the observation that the plants found in the wide areas where seleniferous and normal soils occur in juxtaposition fall into three general classifications with respect to their relation to selenium in the soil as follows:

There was (1) a group of species rarely found outside of the seleniferous areas and capable of absorbing selenium readily and in relatively large quantities. "Since analyses show these plants to be consistently high in selenium and to be growing vigorously even with a very high content, it seems possible that selenium may be of importance to their physiological processes." This possibility is rendered the more probable by the observation that, "in almost every location where these highly selenized plants have been found on seleniferous soil, they have been wholly absent or very rare on adjacent nonseleniferous areas." Among these are *Astragalus racemosus*, *A. pectinatus*, *A. bisulcatus*, *A. carolinianus*, *Stanleya pinnata*, *S. bipinnata*, *Aplopappus fremonti*, and *Xylorrhiza parryi*.

There were also found "(2) plants that are able to absorb moderate, or even large, quantities of selenium without severe injury. Such plants are found widely distributed on both seleniferous and nonseleniferous areas. Among such plants are white wreath aster, blue aster, turpentineweed, sunflower, western wheatgrass (*Agropyron smithii*), and perhaps others. Included in this group are the common cereals wheat, rye, barley, and corn. To what extent the growth of such plants is retarded by the presence of small quantities of

selenium is not known, but it is certain that there is a rather low tolerance limit for the soil.

(3) Plants that have a very limited tolerance of selenium and are able to absorb only small quantities when grown on seleniferous soils: In places where the concentration of selenium in the surface soils is high these plants either do not appear or they are of limited occurrence and make poor growth. The most notable examples of this group are buffalo grass and the grama grasses *Bouteloua gracilis* and *B. curtipendula*."

Within the pH range of the soils examined (7.5 to 8.4), the soil reaction appeared to have little influence upon selenium absorption.

Commercial fertilizers, H. R. KRAEBILL ET AL. (*Indiana Sta. Circ. 229 (1937)*, pp. 75, figs. 2).—In addition to the usual report on the analysis of 1,493 inspection samples, this circular tabulates the average composition of the common fertilizer materials; tonnages of the analyses sold in largest quantities; tonnage, retail value, and pounds per ton of plant food; tonnage sales of low and of high analysis fertilizers for the past 22 yr.; etc.

AGRICULTURAL BOTANY

Range plant handbook (*U. S. Dept. Agr., Forest Serv., 1937*, pp. [839], figs. [296]).—"Repeated requests from field officers of the Forest Service for an accurate publication, readily consultable under field conditions, in as simple language as possible, which could be assembled as desired, and be easily revised, were the genesis of this loose-leaf range plant handbook. Its intended audience is primarily busy field administrative men who are not specialists in botany; its chief purpose is twofold: (1) To evaluate for such persons, in as succinct, understandable, complete, and useful form as possible, the relative importance of some 300 or more of the outstanding 'key' plants of western ranges as regards grazing, watershed protective cover, recreational, and other uses; and (2) to enable the ready field identification of these plants in order to insure the correlation of the proper management data with each species. . . . This handbook presents 339 generic and specific write-ups, incorporated with which, however, are notes on over 500 additional species. The main treatments include 98 grasses, 8 grasslike plants (chiefly sedges and rushes), 137 range weeds (nongrasslike herbs), and 96 browse plants. Because of the loose-leaf structure of this handbook, the text and illustrations are not paged. Each plant discussion has its own symbol (G1, G2, etc., for grasses; GL1, GL2, etc., for grasslike plants; W1, W2, etc., for range weeds; and B1, B2, etc., for browse). Gaps which appear in the symbol sequences are by way of provision for the possible future inclusion of some 173 other plants of material range importance."

An index to common and scientific names is provided.

Aquatic vegetation of the Susquehanna and Delaware areas, W. C. MUENSCHER (*N. Y. State Conserv. Dept. Ann. Rpt., 25 (1935), Sup., pp. 205-221*).—This study by Cornell University was confined mainly to the larger lakes, reservoirs, and a few ponds of special interest. Lists are included of the common aquatic plants in some lakes of the eastern and western parts of the Susquehanna and of the Delaware watersheds, and an annotated list supplies an inventory of the 136 kinds of plants found, together with notes on their general distribution and abundance in the watersheds, the last named list being arranged by plant families.

Keys to woody plants, W. C. MUENSCHER (*Ithaca, N. Y.: [Author], 1936, 4. ed., rev., pp. 105, [figs. 3]*).—This contribution by Cornell University is a revision of the work already noted (*E. S. R., 49, p. 426*).

Prospects for a natural system of classification of bacteria, A. J. KLUYVER and C. B. VAN NIEL (*Zentbl. Bakt. [etc.]*, 2. Abt., 94 (1936), No. 19-23, pp. 369-403, fig. 1).—The authors discuss the motives for a renewed discussion of the subject and the general principles of bacterial classification, give a critical examination of recent contributions to the subject, and present an outline for "a rational system for bacterial classification on the basis of our present knowledge." Tabular presentations are also included, and lists of tribes and genera, with diagnoses of the latter, are appended.

Some observations on the natural bacterial system proposed by A. J. Kluyster and C. B. van Niel [trans. title], S. ORLA-JENSEN (*Zentbl. Bakt. [etc.]*, 2. Abt., 95 (1937), No. 21-26, pp. 478-482).—The author offers comments on the system of bacterial classification proposed by Kluyster and van Niel and noted above.

The nutritional requirements of bacteria, W. BUEBOWS (*Quart. Rev. Biol.*, 11 (1936), No. 4, pp. 406-424).—This is a general review (with bibliography) centered principally around the indispensable elements, growth accessory substances, essential substances, and growth-stimulating substances as affecting bacterial metabolism.

Some heavy metals necessary for the culture of *Aspergilli* and the procedure for freeing nutrient solutions from traces of them [trans. title], T. SAKAMURA (*Jour. Faculty Sci., Hokkaido Imp. Univ.*, Ser. V, 4 (1936), No. 3, pp. 99-116, figs. 2).—*Aspergillus niger*, *A. oryzae*, and *A. tamarii* were used in the physiological studies reported.

The action of copper and manganese upon the formation and color of conidium of some species of *Aspergillus*, F. YOSHIMURA (*Jour. Faculty Sci., Hokkaido Imp. Univ.*, Ser. V, 4 (1936), No. 3, pp. 117-139, pls. 6, figs. 37).—The proper combination of copper (or zinc) and manganese gave rise to the formation of normal conidium-bearing heads, while omission of either of the two caused a reduction in sporulation and an abnormal development of the conidial heads. Transitions from conidial to spherical cell formation were induced when the amount of manganese was varied, rendering it probable that an intimate relation exists between these two tendencies. Manganese also extended the pH limits for growth on the acid side. Copper was found important for sporulation and for the development of pigment in the conidia. Diminution of the amount of sugar also favored sporulation.

Absorption of manganese by plants.—II, Toxicity of manganese to various plant species, C. OLSEN (*Compt. Rend. Lab. Carlsberg, Sér. Chim.*, 21 (1936), No. 9, pp. 129-145, figs. 7).—Grown in water cultures, different plants reacted very differently to increasing concentrations of manganous sulfate, the species used being *Lemna polyrrhiza*, *Senecio silvaticus*, *Hordeum distichum*, *Sinapis alba*, *Zea mays*, and *Deschampsia flexuosa*. The indications are that the amount of dissolved manganese compounds in a strongly acid soil plays an essential role as a growth-inhibitory factor. The fact that only a small number of species can thrive on strongly acid soils is due not only to the high H-ion concentration per se but also to the fact that manganese is so poisonous to most species that they cannot tolerate the amounts absorbed from such soils. Possibly the calcium-ion concentration of culture solutions modifies the toxic effect of manganese, as it has been demonstrated that its ions are antagonistic to manganous ions.

[The relation of boron and iodine to plant growth] (*Kentucky Sta. Rpt.* 1936, pt. 1, pp. 21, 22, 23, 24).—Brief reports are included of studies on the relation of boron to plant growth and on the effect of iodine on the growth of tomatoes, buckwheat, and tobacco.

The reaction of greenhouse plants to gas in the atmosphere and soil, P. R. KBONE (*Michigan Sta. Spec. Bul.* 285 (1937), pp. 35, figs. 32).—Injury resulted from natural gas from Texas and Michigan in the greenhouse air, although higher concentrations were required than for manufactured gas. Tomato, mimosa, geranium, ageratum, coleus, and beleperone plants and cut stems of bougainvillea, Clarkia, and stocks exhibited decided injury from natural gas at 1:200, while Clarkia and bougainvillea were injured at 1:400 for 72 hr. Other plants gave little or no evidence of injury at the latter exposure. In artificial gas at 1:30,000 for 24 hr., injury became apparent on tomato, achyranthes, coleus, mimosa, and geranium, and at longer exposures all of the plants tested were injured. Ethylene is generally conceded to be the most important constituent of gas introduced into the air, as far as plant injuries are concerned.

Some of the foliage symptoms included epinasty, yellowing, premature abscission or defoliation, leaf curling, retarded growth, stimulation of latent buds, and growth of short, weak side branches. When the gas is in the soil the symptoms include swelling of the region back of the root tip and of the hypocotyl, root curling, cracking and sloughing off of the epidermis, and discoloration, hypertrophy, and collapse or death of part or all of the stems or roots.

It is recommended that where gas lines run near a greenhouse a trench be dug along that side of the house, that it be kept open or filled with porous material for aeration during winter, and that young tomato plants be kept in every house as indicators of the presence of escaped gas.

New facts in support of the hormonal theory of plant development, M. C. ČAJLACHJAN (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 4* (1936), No. 2, pp. 79–83, figs. 3).—As a result of experiments with *Perilla nankinensis* and *Helianthus* spp. the author concludes that, together with nutrient substances, there is a movement of "blossom hormone" from the leaves of the stock into the growing points of the engrafted top, where the formation of flowers is induced. This hormone is not considered specific in action for individual species but to be the same in nature in different plants. To this blossom hormone he gives the name "florigen."

Plant hormones and mineral nutrition, G. S. AVERY, JR., P. R. BURKHOLDER, and H. B. CREIGHTON (*Nat. Acad. Sci. Proc.*, 22 (1936), No. 12, pp. 673–678, figs. 2).—The amount of growth hormone present in shoot tips of *Helianthus* and *Nicotiana* was determined by *Arca* coleoptile curvature for seedling plants grown in sand culture under varying conditions of mineral nutrition. It was scarcely detectable in the shoot tips of plants unsupplied with N. It was most abundant with higher concentrations of N and was unaffected by relatively low supplies of Ca, Mg, K, PO₄, and SO₄, or by variations in osmotic pressure of the nutrient solutions. It was much less in the shoot tips of "frenched" than in normal tobacco.

Production and distribution of growth hormone in shoots of *Aesculus* and *Malus* and its probable role in stimulating cambial activity, G. S. AVERY, JR., P. R. BURKHOLDER, and H. B. CREIGHTON (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 51–58, figs. 7).—Using the agar diffusion method and *Avena* coleoptile curvature as a measure of growth hormone production, no indication of its presence was found in dormant winter buds of horse chestnut and McIntosh apple. It was detectable in increasing amounts from the time of swelling of terminal buds, reaching the peak just prior to the most rapid expansion of current season growth and declining afterward. In *Aesculus*, hormone concentration was greater in fruiting shoots than in others, due to continued pro-

duction in the growing fruits. Hormone production appears to be centered in the terminal buds with translocation down the stems into older portions. Cambial activity began at the terminal bud, progressing basipetally as the hormone moved into these regions.

The hormonal influence of β -indolylacetic acid on the growth of isolated roots in sterile organ culture [trans. title], M. GEIG-BUTER and E. BURLET (*Jahrb. Wiss. Bot.*, 84 (1936), No. 1-2, pp. 233-253, figs. 5).—Using a method described, the authors studied the effects of different concentrations of heteroauxin on the growth of maize roots in darkness at 18°-22° C.

The inhibition of roots by growth hormone, R. H. LANE (*Amer. Jour. Bot.*, 23 (1936), No. 8, pp. 532-535, figs. 2).—Indole-3-acetic acid inhibited the growth of roots of young *Arca* seedlings without appreciable effect on the coleoptiles, the effect on the roots being about 25 times as great as that of indole-3-propionic acid. The number of roots of oats may be greatly increased by indoleacetic acid.

The cotyledon petioles of the Viciae as indicators for the correlative inhibitory effect of growth-promoting substance [trans. title], R. DOSTÁL (*Planta, Arch. Wiss. Bot.*, 26 (1936), No. 2, pp. 210-221, figs. 12).—*Pisum sativum*, *Vicia* spp., *Lathyrus sativus*, *Lens esculenta*, and *Cicer arctinum* were used successfully in such tests.

The correlation effect of storage organs and growth-promoting substance [trans. title], R. DOSTÁL (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 7, pp. 418-429, pl. 1).—Using tubers of *Scrophularia nodosa*, bulblets of *Circaea intermedia*, and pea seedlings in his study, the author concludes on the basis of the fact that the growth-regulatory effects of the reserves can be supplanted by limited amounts of growth-promoting substance, that such effects must be attributed not to the nutrient materials but to the hormone, which in its action (first in promoting root formation, then shoot formation) corresponds to heteroauxin.

The demonstration of growth-promoting substances for mitosis, using *Saccharomyces cerevisiae* as the test organism [trans. title], K. RIPPEL (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 7, pp. 487-492).—The author differentiates the growth-promoting substances of stretching and of cell division, giving special attention to the latter and using yeast as more suitable than the oat coleoptile for studying this phase of the mechanism of mitosis.

The question of the mitotic and cell-stretching hormones of plants [trans. title], K. RIPPEL (*Planta, Arch. Wiss. Bot.*, 26 (1937), No. 5, pp. 812-815).—In this note the author reviews his own work, noted above, and that of others relative to the relationships of growth-promoting substances to mitosis and cell stretching and presents further data, using *Zea mays*, *Urtica dioica*, *Pulmonaria officinalis*, *Pisum sativum*, *Phaseolus multiflorus*, and *Vicia faba*, in addition to yeast, as test plants.

Inactivation of plant growth substance by light, P. R. BURKHOLDER and E. S. JOHNSTON (*Smithson. Misc. Collec.*, 95 (1937), No. 20, pp. 14, pls. 2, fig. 1).—Oat and corn seedlings and terminal shoots of *Nicotiana tabacum* were used in the experiments reported. Sources of light were a mercury quartz arc and a Mazda tungsten lamp. The effects of general and unilateral radiation on the growth substance in coleoptile tips of oats and corn and of light on the growth substance "diffused" into agar in contact with cut surfaces of tobacco shoots and oat coleoptile tips were determined.

"Experimental results reported here indicate marked decreases in growth-promoting properties of irradiated tissue and of agar blocks containing growth substance. When so great losses occur under the influence of controlled radiation as mentioned, it is not probable that translocation of the active material

should play any prominent role in growth phenomena at the same time. Under some circumstances, e. g., low light intensity, it may be that more growth substance is moved than is destroyed in the plant. It appears from the experimental evidence presented in this paper that light of high intensities has a destructive or inactivating action on plant growth substance, which is of great importance for phototropism and morphogenesis."

Auxins and the growth of roots, K. V. THIMANN (*Amer. Jour. Bot.*, 23 (1936), No. 8, pp. 561-569, figs. 3).—Differences between *Avena* and *Pisum* roots in their responses to indole-3-acetic acid appear to be based mainly upon differences in their normal auxin content, low concentrations of auxin applied to roots already poor in auxin possibly causing an acceleration of growth. In roots rich in auxin this cannot occur, and in such roots auxin is held not to be a limiting factor in root branching.

The role of auxin in leaf development in Solidago species R. H. GOODWIN (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 43-51, figs. 10).—In *S. sempervirens* the seedling rosette has fewer and larger leaves than in *S. rugosa*, and only one leaf is rapidly elongating at a given time. Experiments showed that such a leaf retarded the development of the younger leaves and produced larger amounts of auxin than leaves at any other stage. In *S. rugosa* auxin production was less and probably insufficient to cause periodic retardation. In each species, however, the auxin production per unit of fresh leaf weight appeared greatest in the youngest leaves.

The action of β -indolylacetic acid on the development of seedlings [trans. title], T. SOLACOLU and D. CONSTANTINESCO (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 7, pp. 437-440, figs. 2).—Studies of the effects of heteroauxin on seedlings and seedling fragments of *Ricinus communis* and *Phaseolus vulgaris* are reported.

The influence of bios on nodule bacteria and legumes.—A, **The influence of bios on legume seedlings**, D. G. LAIRD and P. M. WEST (*Canad. Jour. Res.*, 15 (1937), No. 1, Sect. C, pp. 1-6, figs. 2).—The concentration of crude bios 2 causing maximum hypocotyl bending in red clover seedlings was observed to be about four times that required to induce optimum stimulation in nodule bacteria. When plants were allowed to start in an unenriched medium superimposed on a layer of agar enriched with crude bios 2, no upward bending of the roots occurred as they reached the bios layer. Bios 2 (b) alone appears to be the factor responsible for the hypocotyl bending. Bios 1, bios 2 (a), pantothenic acids, various amino acids, and miscellaneous compounds tested did not appear active in this respect. Heteroauxin, like bios 2 (b), prevented the hypocotyls from entering an enriched medium. While the two substances induce a certain similarity of physiological effect, they cannot be considered identical, and chemically they are distinct.

A drop of bios 2(b) placed on the sensitive lining of a bean pod induced rapid cell multiplication, and similar though somewhat less distinct results followed the pricking of such tissue with a pin. These results are believed to strengthen the theory that bios possesses the properties of a "wound hormone".

Vitamin B₁, a growth factor for higher plants, J. BONNER (*Science*, 85 (1937), No. 2198, pp. 183, 184).—Using excised pea root tips in a pure synthetic medium, it was shown that growth ceased completely in the third passage to fresh synthetic medium. Active root growth, however, was maintained if 0.2 γ per cubic centimeter of crystalline B₁ was added. Even 0.002 γ produced marked stimulation.

The dependence of growth on assimilation, H. CORDES and F. LATBACH (*Jahrb. Wiss. Bot.*, 84 (1936), No. 1-2, pp. 223-232).—Besides its dependence on the concentration of growth-promoting substance, growth in the organs of the plant stem also depends on a second growth factor, the formation of which is bound up with the carbohydrate metabolism, i. e. with the presence of assimilatory products.

The yearly cycle in the physiology of trees, G. W. SCARF (*Roy. Soc. Canada Trans.*, 8. ser., 30 (1936), Sect. V, pp. 1-10, figs. 2).—The author discusses seasonal changes in growth activity, water relations, food reserves, and in the properties of the protoplasm.

Environment, inheritance, and physiological aspect, I, II [trans. title], C. MONTFORT (*Jahrb. Wiss. Bot.*, 84 (1936), No. 1-2, pp. 1-57, figs. 13; 84 (1937), No. 4, pp. 483-516).—Two papers are presented.

I. *Death due to light and resistance to strong light in assimilatory tissues.*—These phenomena were studied in their relations to color type, to previous history, and to constitutional adjustment in algae of the three color classes from qualitatively and quantitatively very different light climates exposed to diffuse and to direct sunlight. Comparison of the succeeding light-assimilation curves, as well as the time curves, led to the separation of definite reaction types, which are discussed.

II. *The significance of the natural light field for the specific photochemical action of definite radiations.*—Studies are reported of the range of light absorption by plants in relation to that of its specific photochemical effects (viz, the physiological effects of light from different parts of the spectrum in relation to plastids carrying different pigments), the ranges of specific photochemical activity as determined by the light previously supplied, and observations on the unique position of photosynthesis as compared with light-catalyzed stimulatory reactions in general.

The thermal relations of plants [trans. title], B. HUBER (*Naturw. u. Landw. [Freising]*, No. 17 (1935), pp. 148, figs. 38).—This monograph takes up the subject under the factors determining plant temperatures (the temperature of the environment, heat from radiation, cooling through transpiration, and respiratory heat); plant temperatures as actually observed, including various organs (leaves, twigs, buds, and stems), habitats, and climatic conditions; and the biological significance of the thermal economy of plants under maximum and average temperatures.

A bibliography of nearly 12 pages is included.

Investigations of the ecology of photosynthesis in native woody plants of forest and garden [trans. title], H. F. NEUBAUER (*Gartenbauwissenschaft*, 10 (1936), No. 3, pp. 380-421, figs. 21).—This investigation involved the development of methods and studies of the effects of environmental factors on photosynthesis in various trees and shrubs (e. g., beech, hornbeam, oak, elm, bird cherry, alder, hazelnut, Japanese quince, currants, etc.)

Effect of light and of ethylene chlorhydrin on the citric acid content of Bryophyllum leaves, J. D. GUTHRIE (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, pp. 283-288, fig. 1).—Citric acid normally increased fivefold during the night, but ethylene chlorhydrin treatment caused a decrease in citric acid in the dark and a consequent increase in the pH of the juice.

Investigations of the influence of light factors on the growth and development of some summer annuals [trans. title], L. KOPETZ (*Gartenbauwissenschaft*, 10 (1936), No. 3, pp. 354-379, figs. 5).—The author's experiments relative to the effects of length of day were performed on peas, lettuce, spinach, and soybeans.

The metabolic changes in seedlings exposed to one-sided illumination [trans. title], P. METZNER (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 7, pp. 455-471, figs. 2).—As in geotropic stimulation, it was found that after unilateral lighting of the hypocotyls of *Helianthus*, metabolic differences appeared in the stimulated side, including changes in sugar content, acidity, and catalase activity.

The effect of street lights in delaying leaf-fall in certain trees, E. B. MATZKE (*Amer. Jour. Bot.*, 23 (1936), No. 6, pp. 446-452, figs. 6).—"Street lights in the City of New York cause a retention of the leaves of certain trees: Carolina poplar (*Populus canadensis*), London plane (*Platanus acerifolia*), sycamore (*P. occidentalis*), and crack willow (*Salix fragilis*). Illuminated portions of a tree retain their leaves; shaded portions of the same tree do not."

The mechanism of the germination-promoting effect of the soil [trans. title], H. BOERSS (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 7, pp. 472-486, figs. 5).—On the basis of tests with seeds of *Vaccaria pyramidata*, it is concluded that the germination-promoting effect of the soil is due not to the presence of any stimulating factor but rather to the removal of an inhibitory substance from the seeds by the adsorptive power of the soil complex. Other contributory factors are also discussed.

On the relation between the ripening stages of the maize-seed and its germination, T. KOSHIMIZU (*Bot. Mag. [Tokyo]*, 50 (1936), No. 597, pp. 504-513, figs. 8).—The seeds on an ear not fully mature were found to differ in the degree of ripeness, and premature germination depended largely on the stage of ripeness and on the treatment given the individual seeds after gathering. The growth of embryos washed free of endosperm juice was much more rapid, the endosperm apparently containing a germination inhibitor. Details of the results are discussed.

The influence of glucose on the production of rootlets by fragments of embryos isolated from nongerminated seeds of *Phaseolus vulgaris* [trans. title], T. SOLACOLU and D. G. CONSTANTINESCO (*Compt. Rend. Soc. Biol. [Paris]*, 121 (1936), No. 12, pp. 1212-1215).—Data are presented on the mechanism of root formation.

The relation of organ size to tissue development in the stem, E. W. SINNOTT (*Amer. Jour. Bot.*, 23 (1936), No. 6, pp. 418-421, figs. 4).—In *Todea hymenophylloides*, *Datura stramonium*, and *Pinus strobus*, the relative sizes of pith, vascular cylinder, and cortex were compared in stems of different sizes. Changes in proportions were found to be regular and specific, pith increasing most rapidly.

The optical demonstration of turgor stretching [trans. title], A. FREY-WYSSLING (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 7, pp. 445-454, figs. 5).—To determine in how far the cell wall cooperates passively or actively in the growth stretching of cells, the author used filaments of *Dactylis glomerata* and *Arrhenatherum elatius* and dried material of *Anthoxanthum odoratum*. He concludes that both factors act together, and that the optical test described permits a demonstration as to whether the active cell-wall growth or the passive turgor stretching predominates in any one case.

Studies on the refractive indices of expressed juice in wheat seedlings, K. EBIKO and Y. WATANABE (*Saghalien Cent. Expt. Sta. Rpts.*, 1. ser., No. 5 (1935), pp. 127-147, pls. 6, fig. 1; *Eng. abs.*, p. 147).—The refractive indexes averaged higher for winter than for spring varieties and for hardy than for nonhardy varieties. No accurate correlation was noted between the content in total solids of the expressed juice as measured by the refractometer and the monosaccharide content of seedling tissues as shown by chemical analysis.

The effect of potassium supply on the water relations of foliage leaves, L. G. G. WARNE (*New Phytol.*, 35 (1936), No. 5, pp. 403-417, figs. 4).—Using sea-kale beet (*Beta cicla*), an additional potash supply induced an increased water content in the leaves when expressed on an area basis and an increase in their potash content which was greater when the potash was supplied as sulfate than as chloride. The leaf content of sulfate or chloride was increased only when the potash was supplied in these forms, respectively. Increases in the potash supply also effected increases in the amount of water imbibed by dried-leaf material, apparently due solely to increases in readily soluble hygroscopic substances.

Additional potash effected an increase in cell size and a decrease in stomatal frequency, and differences in the transpiration rates of pot-grown plants were entirely accounted for by the differences in stomatal frequency. Diurnal changes in stomatal aperture were unaffected by the level of the potash supply. There was no evidence that the osmotic pressure of the cell sap in immature leaves was the factor determining the ultimate size of the leaves.

The blastomycetic method of determining the assimilability of phosphates [trans. title], G. LUCCHETTI (*Bol. R. Ist. Super. Agr. Pisa*, 11 (1935), pp. 10-25, figs. 2).—Results are presented with a modification of the method using the fermentation reactions of *Saccharomyces cerevisiae*.

The migration of solutes, T. G. MASON and E. PHILLIS (*Bot. Rev.*, 3 (1937), No. 2, pp. 47-71).—This is a rather detailed critical discussion of existing experimental evidence and resulting conclusions relating to the translocation of solutes in plants, with 53 citations. Section A deals with the export of mineral elements from the root, B with the export of carbohydrate and mineral elements from the leaf, and C with the interchange of solutes between tissues.

Mineral nutrition and seasonal growth of *Ageratum* in sand cultures with auto-irrigation, W. L. NOBES (*Amer. Jour. Bot.*, 23 (1936), No. 8, pp. 545-555, figs. 3).—In an extensive series of studies, "ageratum plants were grown 45 days in automatically wick-irrigated sand cultures in a greenhouse at Baltimore at five different seasons of the year. Nineteen different initial fertilizer treatments were compared in each of the five series." Although there was considerable unexplained variability in the yields, there was no evidence that the order of productivity of the 19 soils tested varied with respect to season.

Micellar structure of the tracheide wall in certain woods in relation to morphogenetic and mechanical factors, J. C. MARY (*New Phytol.*, 35 (1936), No. 5, pp. 432-455, pls. 2, figs. 6).—The correlation of percentage of longitudinal shrinkage over a given range of percentage fiber saturation with the mean slope of certain spiral slits and microscopic fibrillae in the tracheid walls of 16 species of coniferous woods was confirmed, and the detailed findings in these and related phenomena are discussed in detail, including comparisons with oak wood.

A special apparatus is described for measuring minute dimensional changes in wood and other rigid hygroscopic bodies with changes in relative air humidity, including thermostatic and hygrostatic control (largely automatic).

Some observations on the problem of vessel length determination in woody dicotyledons, W. R. C. HANDLEY (*New Phytol.*, 35 (1936), No. 5, pp. 456-471, pl. 1, figs. 4).—Using maceration methods, vessel segments were found in both ring and diffuse porous woods which appeared to be vessel terminations. In some cases, when vessels had been injected with suspensions,

similar segments were seen to behave as such at the termination of the injection, but the method of sectioning cannot be relied upon to determine whether injection fluids have reached the end of the vessel.

All the injection tests confirmed the view that there is a fundamental difference in vessel length between ring-porous and diffuse-porous types of wood, and this conclusion was confirmed by a simple experiment with coal gas under pressure.

Regeneration from mutilated leaves in monocotyledons, E. E. KEMP (*Notes Roy. Bot. Gard. Edinb.*, 19 (1936), No. 93, pp. 187-190, pl. 1).—Successful results were obtained with *Gasteria* spp., *Drimiopsis kirkii*, *Sansevieria zeylanica*, and *Zamioculcas* spp. The results indicated that either a meristem is present throughout the leaf before mutilation, or that subsequently certain cells regain a meristematic character.

Stomata and altitude [trans. title], H. SPINNER (*Ber. Schweiz. Bot. Gesell.*, 46 (1936), *Festband Rübel*, pp. 12-27, figs. 8).—The author presents data on the number of stomata per square millimeter on the upper and lower surfaces of the leaves of a large number of plant species at various altitudes.

A new apparatus for constant temperature, R. E. COKER and E. W. CONSTABLE (*Science*, 84 (1936), No. 2191, pp. 581, 582).—This describes a relatively inexpensive multiple-chambered constant temperature apparatus in which a nonfreezing fluid from a single refrigerating chamber circulates through other chambers, each provided with a simple thermostatically controlled heating unit (light bulb).

Stop-cocks for mechanical operation, C. F. WINCHESTER (*Science*, 84 (1936), No. 2185, pp. 443, 444, fig. 1).—In this contribution from the University of California, mild steel stopcocks with cores of chrome steel are described as having advantages over the more usual glass stopcocks.

The electrically driven ultracentrifuge, J. W. BEAMS and L. B. SNODDY (*Science*, 85 (1937), No. 2198, pp. 185, 186, figs. 2).—A "vacuum" type of ultracentrifuge driven by electricity and automatically maintaining constant speed is described.

A simple apparatus for the steam method of softening woods for microscopic sections, G. E. DAVIS and E. L. STOVER (*Ill. State Acad. Sci. Trans.*, 28 (1935), No. 2, p. 87).—A steam boiler of about 1 qt. capacity, fitted with a water gage, an outlet for the steam, and an opening for refilling, permits the playing of live steam on the wood while it is being cut.

Technique for preparing microscopic sections of woody stems and roots, W. W. NEWBY and P. PLUMMER (*Bot. Gaz.*, 98 (1936), No. 1, pp. 198, 199).—The method described is similar to the one used in preparing slides of petrifications. The sections could be examined with an oil immersion lens and photomicrographs made from them, and the best results were obtained without staining.

Metal slide mounts for microscopic objects, W. D. COURTNEY (*Helminthol. Soc. Wash. Proc.*, 3 (1936), No. 2, pp. 72-74, figs. 2).—A description is given of the construction of metal slide mounts in which the specimens are held between two cover glasses.

Recent advances in the standardization and improvement of biological stains, H. J. CONN (*Bot. Rev.*, 3 (1937), No. 2, pp. 72-83).—A historical account of the development of stain certification in America by the Commission on Standardization of Biological Stains is followed by a discussion of recent developments in counterstains and nuclear stains, with references to the literature.

GENETICS

Recent advances in cytology, C. D. DARLINGTON (*Philadelphia: P. Blakiston's Son & Co., 1937, 2. ed., pp. XVI+671, pls. 16, figs. 160*).—In this revision of the work previously noted (*E. S. R., 68. p. 749*), the whole account has been recast in terms of evolution. Mitosis is shown as giving rise to meiosis and sexual reproduction, diploidy to polyploidy in one direction and to complex heterozygosis in another. Structural hybridity is represented as the basis of sexual differentiation, and the conditions of parthenogenesis are deduced from experimental observations of the breakdown of sexual reproduction. As to the other relationships of cell behavior, the most important at present are the mechanical, and special treatment is devoted to arranging our knowledge of chromosome behavior and nuclear and cell division to reveal the laws of movement and to inquire into their causes. "Thus in the cell, mechanics, physiology, and physical chemistry are being brought together to show the unity of living processes."

Chromosome structure in relation to the chromosome cycle, B. P. KAUFMANN (*Bot. Rev., 2 (1936), No. 11, pp. 529-553, fig. 1*).—This is a critical discussion of present conceptions with reference to chromosome structure and chromosome mechanics, accompanied by 127 literature references.

Morphological characters of teosinte chromosomes, A. E. LONGLEY (*Jour. Agr. Res. [U. S.], 54 (1937), No. 11, pp. 835-862, pls. 2, figs. 24*).—Comparisons of the lengths of the chromosomes, the positions of fiber attachments, and the number and position of knobs at midprophase of the pollen mother cells of *Euchlaena perennis*, seven forms of *E. mexicana*, *Tripsacum floridanum*, sorghum, and corn showed that these morphological characters of the chromosomes are of value in studying the relationships of this group of grasses. The comparisons also demonstrated that the chromosome complement of teosintes from southern Guatemala is nearly identical, that northern Guatemalan teosintes are very similar to those of southern Guatemala but have a few characteristics that suggest admixture with corn, and that the chromosomes of annual teosintes from Mexico are almost identical with some of the types of corn. Chromosomes of the tetraploid perennial teosinte are practically knobless, thus setting this species apart from any known annual form. The prevalent terminal knobs of *T. floridanum* and of wild teosintes from Guatemala suggest that terminal knobs may be characteristic of all wild species of the Tripsaceae. Internal knobs on the chromosomes of corn and teosinte were found in certain definite positions in all types examined.

Further notes on pangenesis and the inheritance of acquired characters, C. ZIEKLE (*Amer. Nat., 70 (1936), No. 731, pp. 529-546*).—Continuing the previous studies (*E. S. R., 76, p. 175*), the author cites ancient and medieval accounts of germ cells, originating from almost all parts of the body, to show that the hypothesis of pangenesis can be traced from Hippocrates in the fourth century, B. C., to the nineteenth century.

How to use the specific formula of heredity, H. H. LAUGHLIN (*Natl. Acad. Sci. Proc., 21 (1935), No. 11, pp. 611-616, fig. 1*).—The use of the specific formula of heredity (*E. S. R., 71, p. 29*) as applied to Galton's data on the stature of British people is demonstrated.

The probability-resultant, H. H. LAUGHLIN (*Natl. Acad. Sci. Proc., 21 (1935), No. 11, pp. 601-610, pl. 1*).—Based on race horse data, a demonstration is given of the principles which underlie the calculation of the probability-resultant which is the combined effect of several mutually independent factors on the same measured quality.

The mass-pedigree method in the hybridization improvement of cereals, J. B. HARRINGTON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 5, pp. 379-384).—The merits of the mass-pedigree method are described from experience therewith at the University of Saskatchewan.

Heat induced tetraploidy in barley, F. H. PETO (*Canad. Jour. Res.*, 14 (1936), No. 12, Sect. C, pp. 445-447, figs. 6).—A tetraploid sector on a spike of O. A. C. 21 barley was induced by germinating and growing barley for 7 days at 35° C. Tetraploid and diploid florets from the same spike were compared with respect to chromosome pairing and chiasma formation. See an earlier note (E. S. R., 74, p. 470).

Influence of certain oat varieties on their F₁ progeny, F. A. COFFMAN and H. STEVENS (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 4, pp. 314-323, figs. 3).—A comparison of F₁ oats hybrids with plants of their respective parental lines, made by the U. S. D. A. Bureau of Plant Industry in cooperation with the Idaho Experiment Station, revealed that as measured by their hybrids, oats varieties differ widely, some apparently influencing the size of their F₁ progeny, whereas others do not. The extent of this influence and number of characters affected differ with the variety.

The difference in height between Markton and Black Mesdag and their F₁ hybrid plants was not significant statistically, but the hybrids were significantly taller than varieties crossed with Markton and Black Mesdag. Conversely, Bond hybrids were taller than Bond and more nearly approximated their other parents in height. Markton seemed to lack ability to influence the number of culms per plant in its hybrids, which bore fewer culms than Markton, whereas F₁ hybrids of Bond bore fewer culms than varieties crossed with Bond. Markton and Victoria outyielded their F₁ hybrids and the other parents in order, while Bond hybrids exceeded Bond but most often yielded markedly less than their other parents. Consequently, Bond seemed to depress yield in its F₁ hybrids, the opposite being indicated by results in hybrids of Markton and of Victoria.

Bond resulted from crossing varieties belonging to *Avena byzantina* and *A. sativa*, respectively. Certain characters common to Bond, Victoria, Markton, and Black Mesdag suggest that they all may have a similar origin or all may have resulted from species hybrids, an item of special interest in connection with indications that all apparently influence somewhat the size characters in their F₁ progeny.

Alfalfa inheritance studies in New Jersey, G. W. BURTON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 7, pp. 600-606, figs. 5).—The inheritance of several morphological characters and their relation to yield capacity was studied in 100 F₁ progeny of *Medicago falcata* × Hairy Peruvian alfalfa, grown at the New Jersey Experiment Stations on poor heavy Sassafras gravelly loam in 1-gal. stone jars.

Flower color evidently is determined by three genetic factors, the exact mechanism of inheritance not being traced. The stem length of 6-week-old plants, mature plant height, number of stems per plant, leaf index

$\frac{\text{width} \times 100}{\text{length}}$, leaf size (width × length), percentage of leaves, date of

blooming, seed yield, and root type gave distribution curves closely approaching normal, indicating that a number of genetic factors control expression of these characters. Significant correlation ratio values were obtained between plant yields and each of these characters except flower color. Evidence of linkage between the genetic factors determining yield capacity and plant height, date of blooming, leaf index, and leaf size was presented. That root type is in-

herited was proved quite definitely, and the results indicated that upon the heavier podsollic soils, at least, the well-branched type of root system makes for greater productivity. Those characters and relations studied in field-grown F_2 progenies of this cross and of *M. falcata* \times Hardigan alfalfa generally substantiated the above conclusions.

"Round-leaf" cotton: Notes on the appearance and behavior of a peculiar new strain, H. B. BROWN and J. R. COTTON (*Jour. Heredity*, 28 (1937), No. 1, pp. 45-48, figs. 2).—Characteristics and behavior in crosses with normal and okra-leaf cotton are described for a mutant strain which appeared in 1930 in Express-317 cotton grown at the Louisiana Experiment Station. Bud sports have appeared on the mutant plants several times. The chromosomes are normal and number the same as in upland cotton.

Inheritance of okra-leaf and round-leaf in upland cotton, T. R. RICHMOND and R. E. HARPER (*Jour. Heredity*, 28 (1937), No. 6, pp. 215, 216).—A note on the data reported above.

The relation between genes affecting size and color in certain species of *Nicotiana*, H. H. SMITH (*Genetics*, 22 (1937), No. 3, pp. 361-375, pl. 1, figs. 3).—In populations derived from *N. langsdorffii* \times *N. sanderae*, each color gene studied was found to be linked with genes affecting corolla size. Apparently, a large number of size genes were involved and had effects of comparable magnitude, although none with major effects was detected. Some, if not all, are nondominant in the sense that Aa has less effect than AA . The size genes were proved to act in a cumulative manner. There was no consistent indication of any interaction between the size genes linked with any two color genes. Linkage was found between the self-sterility locus and size genes.

Inheritance of corolla color in the cross *Nicotiana langsdorffii* by *N. sanderae*, H. H. SMITH (*Genetics*, 22 (1937), No. 3, pp. 347-360).—Genetic data derived in studies at Harvard University from *N. langsdorffii* \times *N. sanderae* (Sutton Scarlet) show the manner of inheritance of the following genes:

P, a basic gene from *N. sanderae*, governs the presence of anthocyanin color in the upper surface of the corolla. I_1 and I_2 , dominant, independent cumulative genes from *N. sanderae*, are responsible for most of the segregation of anthocyanin pigment intensity. *P* has a minor lightening effect when heterozygous. *D*, from *N. langsdorffii*, has a diluting effect. *R*, from *N. sanderae*, produces red flower color; rr is purple. E_1 and E_2 , from *N. sanderae*, govern extension of color onto the outside of the corolla, only the double homozygous recessive showing restricted pigmentation. *G*, from *N. langsdorffii*, controls the presence of chloroplast color; Y_1 and Y_2 may modify the shade of green or yellow. B_1 and B_2 , complementary genes from *N. langsdorffii*, cause blue pollen.

Additional evidence is given supporting the linkage between B_1 and the self-sterility locus. Genic associations, indicating possible linkages, were demonstrated between pollen color and intensity, extension and intensity, and between *P* and a plastid modifier. *G* may be located on a chromosome not pairing in the normal manner.

A haploid Marglobe tomato: Practical application of a "short cut" for making pure lines, R. C. C[OOK] (*Jour. Heredity*, 27 (1936), No. 11, pp. 433-435, figs. 3).—Since a haploid plant contains only one set of chromosomes and the doubling of this set should produce a plant homozygous for every gene, the author discusses the possibility of securing absolutely uniform strains of tomatoes by self-pollination of a haploid or by vegetative growth from callus tissue.

A cytological and morphogenetic study of some pineapple varieties and their mutant and hybrid derivatives, J. M. CAPINPIN and G. B. ROTOR, JR. (*Philippine Agr.*, 26 (1937), No. 2, pp. 139-151, pls. 3).—Based on studies at the University of the Philippines of varieties, mutants, and hybrids, the conclusion is reached that the haploid number of chromosomes in the pineapple is 25. The occurrence of abnormal types with 60 and 75 somatic chromosomes is explained on the basis of abnormal gametes on the egg side. The meiotic behavior of the pineapple appeared normal, for in diploid types the 25 bivalents in the heterotypic metaphase appeared to be the regular feature of chromosome conjugation. The genetic aspects of the problem are discussed in some detail.

Natural hybridization and genetics of flickers (*Colaptes*), A. DEARIN (*Amer. Nat.*, 70 (1936), No. 731, pp. 585-590).—Classification was made of the color of the malar stripe, wing, tail, and throat and the presence or absence of a nuchal bar in the yellow-shafted flicker, *C. auratus*, and the red-shafted flicker, *C. cafer*, and 47 hybrids between them. The genes responsible for the differences are postulated.

A repetition of McDougall's Lamarckian experiment, F. A. E. CREW (*Jour. Genet.*, 33 (1936), No. 1, pp. 61-102, figs. 11).—A further report (E. S. R., 71, p. 29) on the repetition of McDougall's experiment involving the inheritance of learning ability in rats, in which the author found that the number of errors did not decrease even after 18 generations.

Comparative study of four high tumor lines of mice, J. J. BITTNER and W. S. MURRAY (*Amer. Nat.*, 70 (1936), No. 730, pp. 443-453, figs. 5).—Study is reported of the relation of age of dam, litter size, and percentage weaned to the development of mammary carcinoma in four strains of mice which have shown high incidence of cancer. There appeared to be no direct relation of the tumor incidence to breeding behavior when the age of the dam is considered (E. S. R., 75, p. 762).

The spontaneous tumor incidence in mice.—I, "Z" stock \times "I" stock, J. J. BITTNER (*Jour. Heredity*, 27 (1936), No. 10, pp. 391-393, fig. 1).—Crosses were made between an inbred strain of mice of which 78 percent of the breeding animals developed mammary tumors and a strain showing internal but no breast tumors. When the female parent in the cross was from the mammary tumor stock, 33 of 36 F_1 females developed breast tumors at an average age of 10.4 mo. In the reciprocal cross, 7 of 10 F_1 females developed internal tumors but no mammary tumors. It is suggested that the maternal nature of the inheritance suggests the operation of extra-chromosomal influences in determining mammary tumors.

The detection of a hereditary antigenic difference in the blood of mice by means of human group A serum, P. A. GOREE (*Jour. Genetics*, 32 (1936), No. 1, pp. 17-31).—Agglutination and absorption experiments were conducted between the human group A serum and the blood cells from three inbred and one heterogeneous groups of mice at the University College, London. The results showed that if the tests were conducted at 37° C., it was possible to distinguish various types of mouse blood. In one cross a strong reaction in ability to absorb agglutinins seemed due to a single dominant gene, but modifying factors were assumed as responsible for the reactions obtained by direct agglutination.

Genetics of pituitary and ovary grafts, L. C. STRONG (*Jour. Heredity*, 27 (1936), No. 6, pp. 218-223, figs. 2).—Tests were made of the ability of ovarian and pituitary grafts from five inbred strains of mice to survive in interstrain crosses by implantation in the testicles. At autopsy after 14 to 53 days intra-

strain grafts usually persisted, as did those made from parental strains to F_1 hybrids, but the interstrain grafts did not persist. It is considered that the genetic basis for the persistence of the grafts is inherited as a dominant, with the number of factors undetermined.

Morphologic reaction of the anterior pituitaries of mature female rats to prolonged injections of pregnancy urine extracts, J. M. WOLFE (*Anat. Rec.*, 63 (1935), No. 1, pp. 3-11).—The influence on the pituitaries of daily injections of 25 rat units of pregnancy urine extract for 140 days to mature female rats was studied at Vanderbilt University. The ovary weights were increased from 150 to 500 mg within 15 to 30 days as estimated from laparotomies. While the weights of the ovaries of some individuals remained stationary after this date, others regressed so that at autopsy the ovarian weights ranged from 25 to 460 mg. Pituitary weights ranging from 10 to 37 mg paralleled the ovarian weights. Vaginal smears were irregular but showed early brief periods of complete oestrus with long dioestrous periods in those females having the largest ovaries. The large ovaries consisted of almost a solid mass of large corpora lutea, and the small ovaries contained more follicles. The pituitaries which had regressed to normal size showed normal percentages of eosinophiles and granules, but these were reduced in the enlarged glands. Basophile cells were depleted of granules and were reduced in all glands.

A comparison of theelin prepared from stallion urine, human urine, and from theelol, with notes on the colorimetric estimation of theelin and theelol. G. F. CARTLAND, R. K. MEYER, L. C. MILLER, and M. H. RUTZ (*Jour. Biol. Chem.*, 109 (1935), No. 1, pp. 213-220).—Comparative tests showed stallion urine and human pregnancy urine to be equally good sources of theelin and that the colorimetric method was of value for the rapid quantitative estimation of theelin and theelol in pure solution and semipurified urine extracts.

Tube-locking of ova by oestrogenic substances, R. WHITNEY and H. O. BURDICK (*Endocrinology*, 20 (1936), No. 5, pp. 643-647).—Experiments with mice showed that 5 rat units of theelin, 0.2 cc of Amniotin, and 0.3 cc of Progynon B injected immediately after copulation caused tube-locking of the ova. It is suggested that excess oestrin secretion may cause sterility in this manner.

The effect of estrin on the prostate gland of the albino rat and mouse, D. WELLER, M. D. OVERHOLSER, and W. O. NELSON (*Anat. Rec.*, 65 (1936), No. 2, pp. 149-163, pl. 1).—The daily injection of 40 rat units of oestrin into normal and castrate male rats and mice caused suppression in the height of the epithelium of the prostate and the size of the prostate glands. Injections of antuitrin-S and male hormone with oestrin prevented the loss in weight and height of the epithelium of the prostate.

Endocrine interrelations during pregnancy, H. SELYE, J. B. COLLIP, and D. L. THOMSON (*Endocrinology*, 19 (1935), No. 2, pp. 151-159, figs. 10).—Studies of the influence of ovariectomy during gestation in the rat showed that the placentae continued in apparent functional condition, but termination of pregnancy was due to partial involution of the uterus causing excess pressure on the gestation sac. The length of the gestation period seemed to be determined by factors inherent in the placenta, and the placenta must produce corpus luteum hormone in view of the condition of the mammary gland in these cases.

Hormones and evolution, O. SWEZY (*Amer. Nat.*, 70 (1936), No. 730, pp. 498-500).—Data are presented from the California Experiment Station showing the

number of ova and primordial follicles in the ovaries of rats, some of which were normal, some hypophysectomized, and others injected with pituitary extracts. The results showed that the number of ova and primordial follicles in the hypophysectomized animals far exceeded the number present in the normals or those injected with pituitary extracts. It is suggested that the pituitary hormones have a depressing effect on the new germ cells. An acid extract of the anterior lobe of the pituitary appeared to have a depressing effect on the rat's hypophysis, as the numbers of ova in two animals so treated were equal to those found in hypophysectomized animals.

The reaction of fish to sex hormones, S. E. OWEN (*Endocrinology*, 20 (1936), No. 2, pp. 214-218).—The use of fish of the bitterling species, *Rhodeus amarus*, for the assay of various concentrations of prolans, theelin, theelol, and antuitrin-S was tested. The results indicate that the female bitterling is refractory to solutions containing up to 50 mouse units of these substances per liter of aquarium water. The male, while reactive, gives inconstant results. Caution is presented regarding the possibility of antihormone interference resulting from repeated use.

The speed of travel of ram spermatozoa, R. W. PHILLIPS and F. N. ANDREWS (*Massachusetts Sta. Bul.* 339 (1937), p. 21).—The speed of travel of spermatozoa in the genital tract of the ewe was 12.4 mm per minute as contrasted with 4.83 mm per minute in vitro.

Observations concerning the mechanics of ovulation in the fowl, R. H. PHILLIPS and D. C. WARREN (*Jour. Expt. Zool.*, 76 (1937), No. 1, pp. 117-136, figs. 2).—From a study by operative technic at the Kansas Experiment Station of 33 normal ovulations in 1- and 2-year-old White Leghorn hens, it was concluded that ovulation was due, at least in part, to pressure resulting from the prolonged tension of the muscle fibers of the follicular membrane, but the stimuli to the contraction of the fibers were not determined. None of the following factors was responsible for follicular rupture: Last-minute deposition of yolk, enzymatic action, vacuolization of cells in the follicular membrane, and blood pressure. Intervals between successive eggs averaged 26.3 hr. and oviposition and the next ovulation, 32.2 min.

FIELD CROPS

[Field crops experiments in Alaska, 1935 and 1936] (*Alaska Sta. Buls.* 5 [1936], pp. 7-16, 17, 22-24, figs. 7; 6 [1937], pp. 5-13, 16-19, 36, 37, figs. 4).—Experiments with field crops (E. S. R., 75, p. 766) continued at the station and Matanuska Substation and reviewed again briefly included variety trials with potatoes, soybeans, forage legumes, and grasses; fertilizer tests with potatoes, brome grass, and wheat; crop rotations; a comparison of warmed (green sprouted) v. unwarmed seed potatoes; a production test with sugar beets; and costs involved in growing peas and rye, oats, oats and vetch, barley, barley and vetch, and potatoes in a rotation scheme and in ensiling and hay-making operations.

[Agronomic experiments in Idaho, 1936], K. H. W. KLAGES, H. L. SPENCE, J. TOEVS, W. A. MOSS, and R. KNIGHT (*Idaho Sta. Bul.* 221 (1937), pp. 16-20, 45, 46, 47, 49, 53-56, figs. 3).—Work with field crops (E. S. R., 75, p. 616) reported on from the station and substations included breeding experiments with winter and spring wheat, corn, barley, oats, alfalfa, Ladino clover, and crested wheatgrass; variety tests with oats, winter and spring wheat and barley, sugar beets, alfalfa, field peas, potatoes, sweet corn strains, and miscellaneous forage grasses and legumes; cultural (including planting) trials with grasses and clovers; fertilizer tests with alfalfa and potatoes; treatment of alfalfa

with gypsum; crop rotations; and weed control, particularly bindweed, quackgrass, and yellow toad flax. Work of the State seed laboratory is also reviewed. Several lines of research were in cooperation with the U. S. Department of Agriculture.

[Field crops experiments in Kentucky] (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 25-27, 34, 35, 36, 37-40, 53-55, 55-57*).—Agronomic experiments (E. S. R., 76, p. 29) reported on from the station and substations included variety tests with corn, timothy, red and white clovers, and lespedeza; breeding work with corn, red clover, and bluegrass; rotation, nitrogen fertilizer, liming, and curing tests, effects of soil nitrogen content, and a study of nicotine content, all with tobacco; fertilized crop rotations; experiments with bluegrass for pasture and seed production; and pasture experiments.

[Field crops experiments in Massachusetts], W. S. EISENMENGER, K. J. KUCINSKI, E. B. HOLLAND, R. W. DONALDSON, A. I. BOLEN, W. G. COLBY, H. M. YEGIAN, E. BENNETT, and W. H. SAWYER (*Massachusetts Sta. Bul. 339 (1937), pp. 8-10, 11, 12, 33, 39*).—Agronomic research again reported on briefly (E. S. R., 75, p. 474) included variety trials with potatoes and alfalfa; comparisons of hay seeding mixtures; a frequency of cutting test with alfalfa; pasture experiments; a study of the carbohydrates of bluegrass; the absorption of iron, copper, manganese, and iodine by food plants; comparison of cropping systems, spacing tests, and effects of preceding crops, all with tobacco; and control of cranberry bog weeds.

[Crops research by the Puerto Rico College Station], F. A. LÓPEZ DOMÍNGUEZ, P. R. KUNTZ, F. CHARDON, F. MÉNDEZ, E. M. SALLÉS, J. P. RODRÍGUEZ, L. A. SERRANO, and C. A. CLAVELL (*Puerto Rico Col. Sta. Rpt. 1935, pp. 6-8, 10, 60-97, 103, 107-109, 109-111, 114, 115, 149-156, 160, 161, 162, 165*).—Further experiments with field crops (E. S. R., 74, p. 189) reported on from the station and the Isabela Substation comprised variety, spacing, cultivation, irrigation, fertilizer, green manuring tests, and breeding work, all with sugarcane; irrigation trials and breeding work with cotton; fertilizer tests with tobacco, yams, and potatoes; and variety trials with tobacco, sweetpotatoes, peanuts, pigeon peas, legumes for green manure, cassava, taro, and yautias.

[Field crops work in Rhode Island] (*Rhode Island Sta. Rpt. [1936], pp. 9-14, 17-19*).—Progress results are reported from variety tests with potatoes, soybeans, and lawn and turf grasses; fertilizer experiments with potatoes, alfalfa, timothy and lawn and turf grasses including Kentucky bluegrass and varieties and strains of bents; spraying tests with potatoes; residual effects from different levels of fertilizer, and of cover cropping with corn, as shown by yields of mixed hay; effects of crops on succeeding crops; crop rotation; breeding work with alfalfa; control of lawn pests, diseases, and weeds; and seed production of bentgrass varieties and strains.

The need for statistical control in soils experiments, R. H. WALKER (*Jour. Amer. Soc. Agron., 29 (1937), No. 8, pp. 650-657, fig. 1*).—The importance of replication and randomization in the design of field experiments, supplemented by appropriate methods of statistical analysis, particularly the analysis of variance method, is emphasized. •

Efficiency in field trials of pseudo-factorial and incomplete randomized block methods, C. H. GOULDEN (*Canad. Jour. Res., 15 (1937), No. 6, Sect. C, pp. 231-241, figs. 16*).—Uniformity data for eight different crops were studied to compare the efficiency of the incomplete and randomized block methods. In general, the incomplete block method gave increases in efficiency, such increases being partially correlated with soil heterogeneity. These increases in efficiency appeared to vary on the average from 20 to 50 percent. In view of

the greater adaptability of these methods to irregularly shaped fields, in addition to greater efficiency, their use can be generally recommended. When the relative efficiency of incomplete and complete block methods was studied in relation to size and shape of plats and blocks, the first method was found to give the greatest gains in efficiency when the incomplete blocks were nearly square and made up of long narrow plats.

A rapid quantitative method of studying roots growing under field conditions, R. EL BLASER, (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 5, pp. 421-423, figs. 3).—A modification and improvement of the method of studying root activity originally described by Sprague (*E. S. R.*, 71, p. 616) is outlined and illustrated in this contribution from the Florida Experiment Station.

Crop rotations, I, II (*Washington Sta. Bul.* 344 (1937), pp. 74, figs. 8).—Crop rotation experiments, 1919-34, supplementing earlier work (*E. S. R.*, 45, p. 436) are reported on, with remarks on agricultural and environmental conditions in the Palouse country. A brief statement on the life and work of H. F. Holtz (*E. S. R.*, 65, p. 100), once active in the project, is appended.

I. *Effect of crop rotations on succeeding crops*, E. G. Schafer (pp. 19-50).—In an experiment to determine the merits of various crops in replacing summer fallow in wheat growing and the effect of various rotations on production of succeeding crops, wheat was grown in most of the 22 rotations and on summer fallow and after various crops in rotation. Field peas, corn, sunflowers, and potatoes replaced summer fallow, and oats, barley, and wheat each replaced spring grain in certain rotations. Results concerned primarily with field peas, 1920-25, have been noted (*E. S. R.*, 55, p. 33).

Winter wheat averaged 31.7 bu. per acre, yields varying from 21.2 to 44.1 bu., after summer fallow 42.4 and 44.1, after field peas 31.6 and 32, after corn from 26 to 31, and after sunflowers 21.2 bu. Spring wheat averaged 22.7 bu., from 19.1 to 21.3 after spring wheat, from 18.1 to 21.3 after winter wheat, 31 and 32.4 after field peas, and 29 bu. after red clover. Field peas averaged 19.9 bu. and after winter and spring wheat 19.3 bu. Continuous corn averaged 25.6 bu., field peas 20.2 bu., and alfalfa 3,837 lb. per acre.

When rotations were compared as to value, spring wheat grown continuously with or without manure left less for the grower than wheat grown in rotation. Straight wheat and summer fallow brought a greater annual return than 3-yr. rotations with grain 2 yr. in succession before corn or summer fallow, but this return was less than half of that from a rotation where field peas replaced summer fallow. In every rotation where spring wheat followed winter wheat, returns were lower than where field peas, corn, or summer fallow was used. Two grain crops in succession, whether wheat, oats, or barley, lowered the net returns. Continuous alfalfa gave slightly smaller returns than rotations with sweetclover and greater than those containing red clover. Winter wheat, field peas, spring wheat, corn gave the best return of rotations in which field peas appeared not oftener than once in 4 yr. Comments are also made on the value of crop residues, conserving soil, choosing rotations, and climatic limitations.

II. *Effect of crop rotations on productivity of the soil*, L. C. Wheeting and S. C. Vandecaveye (pp. 51-73).—The effects of several crop rotations, 1919-31, on yields, on the quality of wheat, and on the productivity of Palouse silty clay loam are reported.

Average yields in the several rotations were (1) continuous wheat 25.3 bu.; (2) wheat 44, fallow; (3) wheat 36.6 and field peas 20.8; (4) oats 51, field peas 21, and wheat 33.5; (5) alfalfa 2.47 tons and wheat 33.4 bu., the average of several rotations; (6) field peas 17, red clover green manure 2 yr., and

wheat 3 yr. 30.2; (7) field peas 25.4, sweetclover green manure 1 yr., and wheat 2 yr. 33.9; and (8) winter wheat 37.1 bu., vetch. The last rotation was dropped because of difficulty in eradicating volunteer vetch after plowing. Nitrogen content and quality of wheat, as indicated by yellow berry counts, were closely correlated, $r = -0.7904 \pm 0.019$.

The greatest wheat yield per crop came from the wheat-summer fallow rotation, yet the field peas-wheat rotation proved most productive in income per acre. All rotations containing two or more different crops except the field peas-red clover-wheat rotation also showed greater acre returns than the wheat-summer fallow rotation.

The nitrogen and carbon contents of the soil in different plats under the same system of management varied greatly but were good on all plats. Nitrogen in relation to carbon was reduced under continuous wheat and increased under the wheat-summer fallow rotation. No clear-cut relationship was evident between the treatment and the present soil condition, so far as total nitrogen and organic matter were concerned. Soil loss by erosion was small, being worst under the wheat-summer fallow system. Vegetation and crop residues covering the soil during winter when erosion is greatest retarded run-off and increased the rate of water absorption.

Crop rotation and tillage experiments at the Northern Great Plains Field Station, Mandan, N. Dak., J. T. SAEVIS and J. C. THYSSELL (*U. S. Dept. Agr., Tech. Bul. 536 (1936), pp. 76, figs. 14*).—Yields of several important field crops grown from 1915-1934 in a number of crop rotations and receiving various tillage treatments, manure, and green manure are reported and analyzed. Information is also included on agriculture in the section, soils, climatic, seasonal, and other environmental conditions, and on weeds common in the rotations. Early results, 1915-22, have been noted (*E. S. R.*, 53, p. 132).

Average acre yields were for corn 26.8 bu., spring wheat 15.8, oats 32.4, barley 19.4, flax 4.5, potatoes 113.5, winter rye 11.6 bu., and alfalfa 0.75 ton, sorgo 3,443 lb., and corn fodder 3,624 lb. Respective average yields on disked corn ground and on summer-fallowed land were for spring wheat 15.2, 19.8 bu.; oats 31.8, 45.9; barley 21, 28.1; flax 5.7, 4.3; and winter rye 13.9, 21.6 bu. Continuous corn averaged 29.8 bu. and corn on summer-fallowed land 32.5 bu.

Results with corn showed that spring plowing generally is more desirable than any other method under trial. However, in very favorable seasons the yield on fall-plowed land might equal or exceed that on spring-plowed land. Both summer-fallowed and corn ground are better adapted for small grain production. Subsoiling in addition to fall plowing involved more labor and has not increased yields. Spring listing has several advantages and should be practiced on soils in danger of blowing.

Spring wheat in this section should preferably be grown on disked corn ground where the corn can be used as feed for livestock. For wheat-growing alone, summer fallow and wheat would be better, provided wind erosion can be controlled. Wheat on summer-fallowed soil, for the year of crop, surpassed all other methods except disked potato ground. Subsoiling and listing showed no advantage over other tillage practices.

For oats, the most desirable tillage method available in considerable acreage is disked corn ground, but this is usually sown to spring wheat. Oats, like barley, usually is not valuable enough to justify summer fallowing. In rotation with corn and wheat, oats should be planted on spring plowing after wheat and in case feed grain is important and no cash crop is grown, oats should go on disked corn or summer-fallowed ground. Barley in a rotation with corn and oats should be on spring-plowed land after oats. In a feed

rotation, if much corn is needed for silage, both oats and barley could be grown on disked corn ground.

Flax has made highest yields on disked corn ground, spring-plowed corn ground, and either alfalfa or brome-grass sod. On old land, flax apparently has better chances of success if sown on corn stubble or on sod of cultivated grasses. Winter rye has produced highest on disked corn and on summer-fallowed ground. It is usually drilled into grain stubble throughout the area. but station results show that somewhat better results are obtained from plowed stubble.

Winter wheat sown each year usually winter-kills and has not succeeded under any method of tillage. Alfalfa, brome-grass, potatoes, sorgo, and green-manure crops also have been grown in the rotations. Land on which green manures were plowed under was not superior to summer-fallowed land for production of wheat or oats.

Crop regions in Montana as related to environmental factors, L. P. Rerrz (*Montana Sta. Bul. 340 (1937), pp. 84, figs. 34*).—Data are presented relative to certain environmental factors as they occur in varying magnitude in different parts of Montana, the regions of production of important crops in the State are indicated, and relationships between crop distribution and various environmental factors are pointed out. Factors described in some detail include altitude, precipitation, temperature, storm paths, wind, snow cover, and hours of sunshine.

Montana may be divided into three climatic zones. In the western zone, west of the Continental Divide and characterized by Pacific coast type of seasonal distribution of annual precipitation, relatively warm winters and cool summers, with less wind, and a narrower range of climatic extremes than the central-mountain and plains zones, in order, fruit and certain truck crops succeed. The central-mountain zone, which in general lies from the Continental Divide eastward to and somewhat beyond the 4,000-ft. contour line, has intermediate seasonal distribution of annual precipitation with from 55 to 70 percent falling in the six summer months and the greatest amount in May and June. Average temperatures resemble those of the western zone but with greater extremes. Annual crops and many annual plants do well. The plains zone includes eastern Montana below the 4,000-ft. contour line and closely approaches Great Plains conditions. From over 70 to 84 percent of the total annual precipitation falls during the summer months, temperatures are relatively high in summer and low in winter, and wind velocity is greater than in other zones. Annual hay and grain, the principal crops, thrive under favorable conditions.

Corn, which ordinarily needs a frost-free season of 100 days or longer, in Montana is found only at relatively low altitudes. Since about 2,800 heat units per frost-free season are required for early varieties to develop normally and mature in Montana (E. S. R., 35, p. 338), corn is practically excluded from crops grown above 3,500-ft. altitude except for fodder. Spring wheat seems to be excluded from areas over 5,500 ft. high, where the frost-free season is shorter than 95 days, or where moisture is deficient, although early maturing varieties have allowed production at high altitudes and where short seasons prevail. Winter wheat is grown mainly in elevations not over 5,500 ft., where the January average is not under 20° F., the frost-free season 90 days or longer, and where from 55 to 75 percent of annual precipitation falls between April 1 and September 30. Oats and barley grow at somewhat higher altitudes and in cooler regions than spring wheat, but otherwise are similar in limitations. Flaxseed has been grown on newly broken land primarily in northern

and northeastern Montana where the elevation is low, moisture limited, and summer temperature high, but the crop does not seem to be particularly drought resistant.

Sugar beets seem confined to below 4,500 ft. and require a frost-free period of at least 100 days, most of the crop being grown below 3,500 ft. where the season is 120 days or longer. They need irrigation, since normal precipitation does not suffice for profitable yields. Potatoes are grown up to 6,000 ft., and if given enough moisture and 90 days or longer in which to mature, and not subject to excessive summer temperatures, early varieties may give satisfactory yields on good soil.

Hay crops grow at practically all altitudes where soil and moisture permit. Native hay is produced under most conditions because of many species included, and the crop of lower elevations and warmer areas may differ much from hay from high altitudes and in cool areas. Tame hays, as alfalfa, clover, and certain grasses, are limited in distribution by low winter temperatures, dry winters, and low total annual precipitation.

Drought survival of native grass species in the central and southern Great Plains, 1933, D. A. SAVAGE (*U. S. Dept. Agr., Tech. Bul. 549 (1937). pp. 55, figs. 27*).—The preliminary survey of drought injury to native grasses, made at Hays, Kans. (E. S. R., 73, p. 771), in the fall of 1934, was supplemented in May and June 1935 by ecological studies repeated in greater detail at Hays and extended to seven other stations. A large percentage of the native grasses in the region was killed by the severe drought of 1933-34.

The original cover on sandy soils was apparently less than on heavier soils, and after the drought the cover usually was correspondingly less on sand. Buffalo grass and blue grama together constitute more than 90 percent of the total vegetation on all except very sandy soils. On the heavier soils only a few scattering plants of tall grasses survived, principally bluestem (western wheatgrass), sand dropseed, and red three-awn (wire grass). Blue grama, adapted to a much wider range of soil textures than buffalo grass, was an important species on all soil textures in all localities studied. On sandy lands the grass associations consisted principally of blue grama, bluestem, and 11 other grasses.

Although soil blowing and overgrazing were harmful, climatic extremes caused much more injury than was traceable directly to grazing. Grass cover on closely clipped areas was better than on lightly clipped areas at two stations. As grazing was intensified, the ground cover of buffalo grass declined in all areas with severe drought, yet the relative proportion of ground cover represented by buffalo grass increased as grazing was intensified. Buffalo grass was the most abundant grass in pastures on heavier soils, and apparently was benefited indirectly by grazing, when not extreme. Blue grama, while less resistant than buffalo grass to clipping, heavy grazing, and perhaps drought, surpassed all other grasses in these respects.

The ground cover of practically all tall grasses was reduced as grazing was intensified, sand dropseed being least injured. In about the same degree as tall grasses, most perennial and biennial forbs declined under grazing and drought. The annual grasses, such as *Festuca octoflora*, *Hordeum pusillum*, *Panicum capillare*, *Chloris verticillata*, and *Munroa squarrosa*, which represented only a small part of the total vegetation, were, like annual forbs, most numerous on heavily grazed and severely damaged pastures where perennial grasses were covered by wind-deposited soil. Although much of the grass was dead, surviving plants were distributed rather uniformly and might be expected to recover rapidly under favorable climatic conditions.

Symposium on pasture and forage crops (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 6, pp. 427-511, figs. 9).—The papers in this symposium, held at Atlantic City, N. J., on December 29, 1936, included An Inventory of Forage Species and Their Improvement for Pasture in the Northeastern States, by H. B. Sprague (pp. 427-435) (N. J.); Effect of Maturity on Chemical Composition of Leguminous Forage Plants, by A. J. Pieters (pp. 436-440) (U. S. D. A.); The Influence of Grazing Management and Plant Associations on the Chemical Composition of Pasture Plants, by D. B. Johnstone-Wallace (pp. 441-453), The Influence of Stage of Growth of Corn on the Composition of Silage, by R. G. Wiggans (pp. 456-467) (E. S. R., 71, p. 37), and Interpretation of Variations in Plant Composition in Relation to Feeding Value, by L. A. Maynard (pp. 504-511) (all [N. Y.] Cornell); Technic in Pasture Research, by D. A. Brown (pp. 468-476) ([Conn.] Storrs); The Calcium and Phosphorus Content of Pasture Herbage and of Various Pasture Species as Affected by Fertilization and Liming, by W. H. Pierre and R. R. Robinson (pp. 477-497) (W. Va.) (see below); and Modification of Chemical Composition of Pasture Plants by Soils, by A. R. Midgley (pp. 498-503) (Vt.).

The calcium and phosphorus content of pasture herbage and of various pasture species as affected by fertilization and liming, W. H. PIERRE and R. R. ROBINSON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 6, pp. 477-497).—Samples of pasture herbage and of pure Kentucky bluegrass, white clover, poverty grass, and broomsedge, collected 1931-36 by the West Virginia Experiment Station from variously fertilized and limed plats on two different soils, were examined for calcium and phosphorus, and in some cases total nitrogen and "excess base."

Herbage from the unproductive Dekalb silt loam at Morgantown was only 60 percent as high in phosphorus as that from untreated plats of the fertile Huntington silt loam at Moorefield. Liberal fertilization increased the phosphorus content of the herbage to about the same level, but the percentage increases were 101 and 29, respectively. The calcium content of a mixed herbage seemed to be determined largely by the botanical composition of the pasture, in turn related to the lime and fertilizer treatments. White clover and certain common weeds have much higher calcium percentages than the grasses.

When grown in association on a number of untreated and variously treated plats, white clover averaged 88 percent as high in phosphorus as bluegrass, but 248 percent higher in calcium. Phosphorus fertilization increased the phosphorus content of white clover an average of 10 percent v. 40 percent for Kentucky bluegrass. Broomsedge contained from 68 to 86 percent as much phosphorus and from 54 to 76 percent as much calcium as Kentucky bluegrass. The percentage increase in phosphorus from phosphate fertilization was similar for the two grasses. Liming the acid Morgantown plats increased the calcium percentage in broomsedge by an average of 19 v. 36 for bluegrass. Poverty grass averaged less than 70 percent as high in phosphorus as bluegrass on untreated plats, but about 85 percent on plats receiving much phosphorus. The percentage increase in phosphorus content of poverty grass from phosphate fertilizers approximated twice that for bluegrass. Poverty grass was from 49 to 70 percent as high in calcium as bluegrass. The excess base content of white clover was 195 percent higher than of Kentucky bluegrass (46.3 milligram equivalents per 100 g), whereas broomsedge and poverty grass averaged 67 and 62 percent as high as bluegrass, respectively. Broomsedge and poverty grass averaged 76 and 74 percent, respectively, as high in nitrogen as did bluegrass.

Conclusions were that the herbage from many West Virginia pastures may be inadequate for the phosphorus requirements of the grazing animal, but probably contains, in general, enough calcium.

The minimum and average percentages of calcium and phosphorus for Kentucky bluegrass and white clover obtained in this study were compared with values obtained by others and the phosphorus content of bluegrass discussed in relation to Macy's theory (E. S. R., 77, p. 314). Indications are that the minimum percentage of phosphorus for bluegrass in the vegetative stage of growth approximates 0.16 percent and the critical percentage 0.3 percent.

A comparison of grazing and clipping for determining the response of permanent pastures to fertilization, R. R. ROBINSON, W. H. PIERRE, and R. A. ACKERMAN (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 5, pp. 349-359, figs. 2).—In a comparison of methods of determining yields of permanent pastures, made by the West Virginia Experiment Station and the U. S. D. A. Bureau of Plant Industry, 1932-36, yields obtained by clipping permanent grass showed a progressive decrease in relation to yields obtained by grazing with dairy cattle, yet there was a high correlation in any 1 yr. between yields from clipping and from grazing. In a method suggested, clipped yields may be expressed in terms of grazing units. The response to fertilizer and lime treatments determined by the "difference method" of clipping (obtaining the difference between the yields of temporarily enclosed areas and corresponding grazed areas) was a good measure of the response obtained by grazing. The ratio between weight of oven-dry forage obtained with this method and total digestible nutrients calculated from grazing was 1:0.61.

The spacing of corn in the west central Great Plains, J. F. BRANDON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 7, pp. 584-599).—Effects of different spacings of Akron Yellow corn on its yields and the following wheat crop were studied in a 2-yr. rotation of corn and winter wheat at Akron, Colo., by the U. S. D. A. Bureau of Plant Industry, cooperating with the Colorado Experiment Station. From 1924 to 1935, inclusive, 12 crops of corn and 9 crops of winter wheat were grown. Loss of winter wheat crops was attributed to failure of stands through winter killing and insect injury.

The highest 12-yr. average yield of ear corn was 13.3 bu. per acre for plants 24 in. apart in 44-in. rows, a spacing recommended for grain production under similar conditions. The 9.2-bu. average yield from double-spaced rows was 28 percent below the average for 5 spacings in 44-in. row plats. The highest total corn yield, 3,088 lb., was from 12-in. spacing in 44-in. rows, and 18-in. spacing made only a little less. From 12 to 18 in. in 44-in. rows is recommended for silage production in the locality. Corn planted from 30 to 36 in. apart in 44-in. rows averaged about 30 percent ear corn by weight, from 12 to 18 in. about 20 percent, and 24 in. about 25 percent ear corn.

The highest average acre yield of winter wheat for grain, 12.8 bu., came from double-spaced row corn land, compared with 10.8 bu., the average on 5 spacings in 44-in. rows, but the gain in wheat did not more than compensate for the loss in corn. Planting corn in double-spaced rows decreased yields markedly in productive years and did not increase certainty of production in poor years. The total production of ear corn and wheat grain was greatest on land where corn was spaced 24 in. apart in 44-in. rows, and the highest total weights of corn and wheat (grain, stover, and straw) were obtained from land with 12-in. spaced corn in 44-in. rows.

Pure seed requirements in the production of sea island cotton, W. W. BALLARD (*Georgia Sta. Circ.* 113 (1937), pp. 10).—Production of sea island cot-

ton in Florida and south Georgia has expanded rapidly during the past 3 yr., due to favorable seasons and unusually low weevil infestation, yet even if satisfactory yields can be produced permanent establishment of sea island cannot be accomplished unless immediate steps be taken to maintain purity of planting seed. Precautions discussed and indicated as necessary to maintain pure seed include not planting closer than 1 mile from short cotton, roguing at least twice, picking seed cotton in clean sacks, using a clean gin and clean storage for both seed cotton and seed, and organization of a one-variety community. This contribution is in cooperation with the U. S. D. A. Bureau of Plant Industry.

Adapting high analysis and concentrated fertilizers to cotton soils, J. J. SKINNER, H. B. MANF, E. R. COLLINS, E. T. BATTEN, and R. P. BLEDSOE (*Soil Sci.*, 44 (1937), No. 1, pp. 1-22).—Experiments to determine the factors influencing the effects of concentrated fertilizers on cotton and to compare different concentrated fertilizers with standard strength mixtures were conducted by the U. S. D. A. Bureau of Plant Industry, 1925-36, in cooperation with the North Carolina, South Carolina, Virginia, and Georgia Experiment Stations.

On Cecil clay loam at Youngsville, N. C., Cecil sandy clay at Raleigh, N. C., and Norfolk sandy loam at Goldsboro, N. C., concentrated fertilizers (acid and calcium- and magnesium-free) gave as good results as standard fertilizer in the early years of the experiments, but decreased in efficiency as use continued. On fertile Onslow sandy loam at Holland, Va., fertilizers gave good results during the entire 7 yr. tested. Concentrated fertilizers properly supplemented with limestone and, in some cases, with magnesium usually equaled and often surpassed standard fertilizers. The results as a whole indicated that differences in content of minor elements are unimportant in their influence on the relative efficiency of standard and concentrated fertilizers. The nitrogen sources did not vary widely in effects on cotton when the fertilizers were properly supplemented with limestone. The largest yields generally were obtained with concentrated fertilizers containing acid-forming ammonia salts or soluble nitrogen supplemented with limestone, a finding in keeping with previous results cited by Schreiner and Skinner (*El. S. R.*, 73, p. 313).

Properly formulated double-strength fertilizers evidently may be as efficient as single-strength fertilizers. The data indicated that the use of concentrated fertilizers supplemented properly, best applied simultaneously with planting and in bands to the side of the seed, should give good results and reduce the cost of cotton production.

Fertilizer experiments with cotton on heavy irrigated soils, G. STATEN and D. A. HINKLE (*New Mexico Sta. Bul.* 248 (1937), pp. 16, figs. 4).—In a fertilizer test with cotton grown continuously on irrigated soil varying from a very heavy plastic Gila clay adobe to a rather heavy Gila clay loam, 1929-36, 8 yr. of continuous cotton did not cause reduction in yield, trends being generally upward for all treatments. The yield trend for manured plats rose more consistently and faster than for those treated otherwise.

Annual applications of manure at rates of 6.25 tons per acre, 1929-32, and 8.5 tons, 1933-36, increased the average annual yield of lint cotton by 118 lb. per acre (1,030 v. 912 unfertilized), increased average staple length by almost $\frac{1}{8}$ in., produced slightly larger bolls, resulted in a slightly lower lint percentage, and delayed maturity, increasing the late-picked cotton by 5.6 percent. However, these characters were not affected significantly by annual applications of superphosphate 135 lb., ammonium sulfate 150 lb., or a combination of superphosphate 135 lb. and ammonium sulfate 150 lb. per acre when compared with no-fertilizer plats. Potassium sulfate at the rate of 200

lb. per acre, 1936, did not affect any character studied. No fertilizer treatment used seemed to affect prevalence of *Ferticillium* wilt.

Effect of age, condition, and temperature on the germination of flaxseed. A. C. DILLMAN and E. H. TOOLE (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 23-29, fig. 1).—Results of germination tests of flaxseed from 4 to 18 yr. old, of weather-damaged seed, and of seed exposed to high temperatures in the Imperial Valley of California are reported.

In 1936, flax samples grown at Mandan, N. Dak., and from 7 to 14 yr. old. showed very satisfactory germination, while samples from 15 to 18 yr. old were lower in viability, germinating from 50 to 89 percent. Samples grown in 1921 and 1919, respectively, gave a much lower germination than a sample harvested in 1920, a difference possibly due to drought in 1919 and 1921 which forced early ripening before the seed was fully mature. A wet harvest and threshing season in Minnesota and the Dakotas resulted in much weather-damaged flaxseed in 1926. Tests of 41 carlot samples received in Minneapolis indicated that seed of high moisture content, from 10 to 18 percent, was injured in germination.

Flax exposed in a dry condition in the sheaf to the very high summer temperatures of the Imperial Valley was not injured in germination nor in the yield and quality of oil. Germination tests showed that a constant temperature of 35° C. (95° F.) or a temperature of 40° for 6 hr. each day will prevent normal germination of flaxseed. These results appeared to explain failure to obtain a satisfactory stand of flax sown at El Centro, Calif., September 20, 1935, when soil temperatures must have exceeded 100° F.

The development of the oat panicle. O. T. BONNETT (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 12, pp. 927-931, pls. 2).—The principal stages in the formation of the oats panicle and flower were studied at the Illinois Experiment Station by dissecting the growing points and panicles from stems in different stages of development. See also similar studies on barley and wheat (E. S. R., 76, p. 329).

In the first stage of development of an oats stem, leaves and tillers are produced, and in the second stage the internodes of the stem elongate and the panicle and its parts differentiate and develop. Panicle formation is first indicated by appearance of single, lateral, alternate projections arising in the axils of leaf initials beneath the apex of the growing point, which are the primordia of the branches of the first order. Branches of the second and third order arise from the parent axes in the same manner that branches of the first order arise from the main axis. Spikelets differentiate from the tips of the branch primordia, the differentiation beginning first at the apex of the main axis and proceeding basally on the branches of the first order and in sequence on the branches of the second and third orders. The empty glumes are the first of the spikelet parts to differentiate. The flowers of a spikelet differentiate acropetally; and flower parts differentiate in the order lemma, anthers, palea, lodicules, and pistil. In the pistil the order of differentiation is ovary, styles, and stigmas. Since the main axis and all branches terminate in spikelets, a panicle can be called a determinate inflorescence.

A study of the relative adaptation of certain varieties of soybeans. J. M. POEHLMAN (*Missouri Sta. Res. Bul.* 255 (1937), pp. 43, figs. 6).—Morse soybeans have outyielded Virginia soybeans when grown under similar favorable conditions, whereas, in general, Virginia outyields Morse under unfavorable growth conditions. This reversal in relative yields has been associated with a change in growth type in Morse from upright and branching to a low and bushy form. The phenomenon is associated with soil type, but the associa-

tion has not been consistent. Pot experiments involving several soil types, soil and sand mixtures, and soil moisture and fertility levels failed to confirm results of field experiments. The relative significance of season, soil moisture, temperature, and light, especially length of day, in regard to the phenomenon is discussed. Studies of their expressed plant juices (E. S. R., 73, p. 451) revealed no significant differences between the two varieties. It is concluded that more extended and complete study of the various factors involved would be required by this problem.

Soybean production in Michigan, C. R. MEGEE (*Michigan Sta. Circ. 161 (1937)*, pp. 14, figs. 3).—Practical information is given on the status of the soybean crop in Michigan and its uses as an emergency hay crop, for silage, in the form of soybean oil meal, as a supplementary protein feed, soil improver, and as a cash crop, with recommendations on varieties and suitable cultural methods and field practices. Industrial and commercial uses also are listed.

Better planning for field experiments with fertilizers, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 2, pp. 99-109, figs. 2).—Particular attention is given to the design of fertilizer experiments for sugarcane and to the handling of phosphate, potash, and nitrogen problems.

Phosphate deficiency, R. J. B[ORDEN] (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 2, pp. 85, 87-89, figs. 3).—The early, greatly stimulated root and shoot development of sugarcane resulting from the application of a phosphate fertilizer with the seed at planting is illustrated. Lack of stooling is shown to be a rather definite symptom of phosphate deficiency when the green leaf color indicates enough nitrogen.

Improving the protein content of timothy (*Phleum pratense*) by application of soluble nitrogen fertilizers 10 to 20 days before harvest, H. B. SPRAGUE (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 7, pp. 607, 608).—A brief report is made from the New Jersey Experiment Stations on the substantial increase in the crude protein content of timothy obtained by applying different nitrogen carriers from 10 to 20 days before harvest.

The relation of awns to the productivity of Ohio wheats, C. A. LAMB (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 5, pp. 339-348).—An Ohio Experiment Station study on 3,695 bearded and 4,590 beardless spikes of wheat from 8 segregating populations, 1932-34, indicated a probable slight yield increase resulting from the presence of the awn. However, for practical purposes the advantage was negligible, and there seemed to be no reason for carrying awned selections in the breeding nursery. Contradictory evidence of other investigators on the value of awns is also discussed.

Wheat seeding, C. A. LAMB (*Ohio Sta. Bimo. Bul. 187 (1937)*, pp. 115-118).—Essentials for production of superior soft red winter wheat include a variety such as Trumbull, Fulbio, and Gladden; clean seed treated for seed-borne diseases; adequate seedbed preparation and a reasonable fertility level; and planting on or as soon after the fly-free date as possible.

Comparison of the cold resistance of several varieties of winter wheat in transition from dormancy to active growth, H. H. LAUDÉ (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 12, pp. 919-926, figs. 3).—The comparative cold resistance of Minturki, Kanred, Quivira, Turkey, Blackhull, and Harvest Queen winter wheats was studied at the Kansas Experiment Station during transition from the winter to the spring stage of growth, induced by transferring naturally hardened plants in the winter from outdoors to the greenhouse. Although cold resistance was usually lost more rapidly in varieties

possessing greater midwinter hardiness, the contrary was also found. Harvest Queen lost resistance to cold more slowly than the other varieties, and thus retained a relatively high degree of resistance into the spring growth stage. This character may be important in protecting the crop against injury from early spring freezes. No relation between rate of transition and time of maturity was observed.

Cold resistance of winter wheat, rye, barley, and oats in transition from dormancy to active growth, H. H. LATHE (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 12, pp. 899-917, figs. 8).—The changes in cold resistance during transition from dormancy to active growth were studied at the Kansas Experiment Station in wheat, rye, barley, and oats for the 1932-33 and 1933-34 seasons. Transition changes were induced when winter-hardened plants grown outdoors were transferred into a greenhouse with a favorable growth environment. Relative cold resistance and changes in resistance were measured by artificially freezing the plants at various stages in the transition.

Transition under the control provided was faster, but comparable otherwise to winter-spring transition in the field. Temperature seemed to have been the chief factor influencing the rate of transition. Change in cold resistance proceeded at a decreasing rate except for about 12 hr. just after placement in the greenhouse. As soon as the plants were stimulated into activity their cold resistance decreased very rapidly, the rate of change being greatest during the first part of transition and gradually slowing until after 2 weeks little change was taking place. In the hardened condition, Dakold rye was considerably more resistant to cold than Kanred wheat, Tennessee barley, and Sporen oats, in order, but after 9 days in the greenhouse little difference in cold resistance remained. All had lost resistance, and the hardy rye evidently had lost more than the others and wheat more than barley and oats.

The water content of the plants increased and total solids in the sap decreased during the transition, rapidly at first and then slower until about the ninth day, after which little change occurred. The amount of juice expressed from leaves increased at a constant rate throughout transition, suggesting that a change in bound water to free water continued after the maximum water content was attained. Cold-resistance changes were associated negatively with water content, refraction of sap, and pressed juice during the first half of the transition period and similarly associated with pressed juice during the last half.

Increasing the speed of reading germination tests, W. CROSBIE and S. PATRICK (*Farm Res.* [New York State Sta.], 3 (1937), No. 4, pp. 8, 14, 15, fig. 1).—An organic mercury compound diluted with certain dusts, used to treat seeds to be tested for germination, surpassed other materials tried in respect to normal seedling development, germination percentage, freedom from micro-organisms, and cost of application.

The winterhardiness of weeds, S. T. DEXTER (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 6, pp. 512-517).—Samples of rhizomes from fertilized and unfertilized quackgrass, roots of Canada thistle and field bindweed, and crowns of downy brome grass were collected weekly during the fall at the Michigan Experiment Station. Tests indicated that they became more hardy as cold weather came on. Canada thistle was found to be relatively susceptible to injury by freezing. When photosynthesis was prevented in the fall, quackgrass fertilized with nitrogen failed to harden, while unfertilized quackgrass rhizomes hardened considerably, although not as well as if photosynthesis was permitted. Alfalfa roots and crowns could withstand lower temperatures than Canada thistle or bindweed roots. Quackgrass rhizomes from unfertilized

plats were hardier than those from fertilized plats. The applicability of certain of these principles in control of quackgrass on a field scale is discussed.

HORTICULTURE

[Horticulture at the Alaska Station, 1935 and 1936] (*Alaska Sta. Bul.* 5 [1936], pp. 24-26; 6 [1937], pp. 20-22, 26-36, 37-39, figs. 7).—Herein are presented the results of studies upon the variety and culture of small fruits, possible causes of failure of fruit trees to survive, varieties and propagation of ornamentals, varieties and fertilizer requirements of canning peas, effect of fertilizer and variety on the chemical composition of canning peas, and culture and varieties of vegetables.

[Horticultural studies by the Idaho Station], L. VERNER (*Idaho Sta. Bul.* 221 [1937], pp. 35-38, fig. 1).—Brief reports are presented on the results of trials of various fruit species and vegetables on old orchard soil, on apple breeding, on the causes of cracking of sweet cherry fruits, and on the effects of the severe winter of 1935-36 on various fruits such as apple, cherry, plum, and apricot.

[Horticultural investigations conducted by the Kentucky Station] (*Kentucky Sta. Rpt.* 1936, pt. 1, pp. 43, 44, 57).—Included are brief reports on cover crop and cultural trials with apples, on the effect of drought on the soluble nitrogen and phosphate phosphorus content in the conducting tissues of the bean plant, and on methods of planting lima beans.

[Horticultural investigations conducted by the Massachusetts Station] (*Massachusetts Sta. Bul.* 339 [1937], pp. 13, 31, 32, 39, 40, 41, 64-66, 73-85, 91).—Included are brief progress reports on the following studies: Onion breeding, by W. G. Colby and H. M. Yegian; moist mats for clay pots, by L. H. Jones; cold storage of cranberries, by C. I. Gunness, H. J. Franklin, and C. R. Fellers; development of strains of cranberry resistant to false blossom, effects of copper on the growth of cranberry vines, and spraying and dusting of cranberries, all by H. F. Bergman and W. E. Truran; breeding snapdragons for varietal improvement and disease resistance, the effect of nutrients, soil reaction, and light on gardenias, propagation of gardenias and geraniums, and fertilizers for carnations, all by H. E. White; use of tin pots for merchandizing roses and other plants in full growth, and testing of ornamentals for hardiness, both by G. Graves; testing of seed sold in packets, by G. B. Snyder and A. P. Tuttle; varieties of lettuce, sweet corn, and tomatoes, by Tuttle, Snyder, and P. W. Dempsey; varieties and culture of asparagus, and improvement of vegetables by breeding and selection, both by R. E. Young; training of tomatoes, by Young, Dempsey, H. A. Wilson, and Tuttle; Pascal celery storage, by Young; the interrelation of stock and scion in apples, and influence of various clonal stocks on apple varieties, both by J. K. Shaw; tree characters of fruit varieties, by Shaw and A. P. French; genetic composition of peaches, by J. S. Bailey and French; cultural and fertilizer studies with the apple, by Shaw; varieties of fruit, by Shaw et al; fruit bud formation in the strawberry, by R. A. Van Meter; bud mutations in the apple, by Shaw and W. H. Thies; storage of apples, by O. C. Roberts; the removal of arsenic and lead residues, by Roberts and Shaw; nutrition and culture of the highbush blueberry, by Bailey; and causes of premature dropping of the McIntosh apple, by L. Southwick.

[Horticultural investigations conducted by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt.* 1935, pp. 8-10, 98-103, 104, 121-134, 157-160, 161, 162).—Progress reports are presented on investigations relating to fertilizer and shading requirements of coffee, and varieties of coffee, all by J. G. Ar-

rillaga: culture of coconuts, and varieties of pole beans, both by F. Méndez; rootstocks for citrus, propagation of oranges, mangoes, avocados, and miscellaneous fruits, and varieties of mangoes and avocados, all by J. S. Simons; and fertilizer requirements of peppers, tomatoes, and eggplants, varieties of tung-oil trees, culture of onions and garlic, and production of vegetable seed, all by L. A. Serrano and C. A. Clavell.

[Horticultural investigations by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1936], pp. 14-17, 19-25, 29, 30).—In a brief manner there are considered the results of fertilizer studies with various market garden crops, strain and variety tests with various vegetables such as lettuce, cabbage, tomatoes, celery, beets, beans, and spinach, comparison of loam and sandy types of soil for celery and tomatoes, treatment of vegetable seeds and the soil with disinfectants, fertilizer requirements of *Daphne carolin* and other ornamentals, influence of sprays on carbon dioxide assimilation of apple leaves, testing of various apple sprays, effect of spacing on the growth of strawberry plants, carbon dioxide assimilation by the tomato, breeding of blackberries, testing of plum varieties, the nutrition of the blueberry, the culture of *Daphne* and of a bamboo species from China, the growing of poplar for farm wood supply, and the determination of quality in vegetables by physiological methods.

[Horticulture at the Dominion Experimental Station, Summerland, B. C.] (*Canada Expt. Farms, Summerland (B. C.) Sta., Results of Expts., 1932-36*, pp. 4, 6-24, figs. 2).—Included in this report are the results of investigations in orchard soil management, irrigation, variety tests of tree and bush fruits, breeding of fruits, testing of apple and pear rootstocks, planting, grafting, pollination, pruning, fruit thinning, harvesting, storage of fruit, fruit products, vegetable growing, and testing of ornamental plants.

New uses for fruits and vegetables, D. K. TRESSLER (*Farm Res.* [New York State Sta.], 3 (1937), No. 4, p. 11).—Among subjects discussed in this, the second of two articles (E. S. R., 77, p. 189), are the drying of apple sauce, preparation of unfermented fruit and vegetable juices, clarification and carbonation of cider and other juices, preparation of rhubarb juice and fruit-juice concentrates, and of apple pectin.

Cauliflower and heading broccoli production, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 130* (1937), pp. 6, figs. 2).—Brief general information is presented.

The culture of table beets, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 127* (1937), pp. 4).—Information is offered concerning culture, harvesting, marketing, etc.

Production of carrots, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 125* (1937), pp. 4).—Among subjects discussed are soils, varieties, general culture, disease and insect enemies, storage, etc.

Muskmelon breeding a year round project, W. D. ENZIE (*Farm Res.* [New York State Sta.], 3 (1937), No. 4, p. 12, fig. 1).—Following a study of over 200 varieties, breeding was begun in an effort to combine certain desirable characteristics in new seedlings. The program includes inbreeding for two or three generations to secure uniformity and then crossing. A brief description is given of the flowering habit of the muskmelon and of methods employed in producing new varieties.

Production of eggplant, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 131* (1937), pp. 4).—This includes general cultural information.

New York's hop industry is forging ahead, J. D. HARLAN (*Farm Res.* [New York State Sta.], 3 (1937), No. 4, pp. 12, 13, fig. 1).—A steady increase is indicated in acreage and number of hop growers. Wide differences were noted in the lupulin content, suggesting possibilities of varietal treatment, and an increasing interest in cooperative kilns was manifested.

Production and preparation of horseradish, W. R. BEATTIE (*U. S. Dept. Agr. Leaflet 129 (1937), pp. 6, figs. 2*).—This is a presentation of general information.

Rhubarb production, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 126 (1937), pp. 4*).—Brief cultural comments are presented.

Production of spinach, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 128 (1937), pp. 8, figs. 3*).—General information is presented on varieties, soils, fertilizers, culture, harvesting, etc.

A new experiment with tomato plants, C. B. SAYRE (*Farm Res. [New York State Sta.], 3 (1937), No. 4, p. 16, fig. 1*).—In this preliminary discussion the author reports that locally grown greenhouse and coldframe tomato plants showed much better survival than did Virginia- and Georgia-grown plants.

The necessity of minor elements for the growth of tomatoes in a poor soil, J. S. McHARGUE and R. K. CALFEE (*Jour. Amer. Soc. Agron., 29 (1937), No. 5, pp. 385-391, figs. 2*).—A more detailed account than that previously noted (*E. S. R., 77, p. 482*).

Type and severity of fruit cracking in tomato varieties, W. A. FRAZIER (*Amer. Soc. Hort. Sci. Proc., 33 (1936), p. 536*).—Observations in 1936 at the University of Maryland on a total of 70 varieties and strains of tomatoes growing in the field showed appreciable and consistent differences in cracking tendencies in certain varieties. Environmental factors, such as rainfall, were even more potent than varietal. Among the varieties showing deep radial cracking were Marglobe, Bonny Best, John Baer, Nystate, Chalks Red Jewel, and Early Detroit. Most early varieties, such as Earliana, Penn State, June Pink, and Landreth Sunrise, were more susceptible to concentric cracking than were the late varieties. Relative freedom from both radial and concentric cracking was noted in Pear Shaped Red and Brown Special.

The effect of storage on tomato quality, F. C. GAYLORD (*Canner, 85 (1937), No. 7, pp. 12, 13, fig. 1*).—Continued studies by the Indiana Experiment Station (*E. S. R., 76, p. 628*) gave further evidence that tomatoes deteriorate quickly when kept in storage and that the loss is proportional to the percentage of No. 1's. Lots with considerable greenish fruit may actually increase in quality because of ripening after picking.

Fruits, old and new and northern plant novelties, N. E. HANSEN (*South Dakota Sta. Bul. 309 (1937), pp. 16*).—Herein are presented lists of varieties of fruits recommended for planting in South Dakota and notes on fruits, flowers, and field crops regarded as of promise.

Storage experiments with pollen of cultivated fruit trees, B. R. NEBEL and M. L. RUTTLE (*Jour. Pomol. and Hort. Sci., 14 (1937), No. 4, pp. 347-359, figs. 7*).—At the New York State Experiment Station, pollen taken from anthers allowed to dehisce in open Petri dishes was transferred to shell vials loosely stoppered with cotton wool, and these, in turn, were placed in desiccators in a dark storage chamber held at from 2° to 8° C. The desiccators were maintained at calculated relative humidities of 50, 60, 70, 80, 90, and 100 percent. The duration of life was increased as the relative humidity was decreased, and at 50 percent apple and sour cherry pollens showed good germination after more than 2 yr. of storage. The indications were that pear, plum, peach, sweet cherry, and grape pollens would also keep for 2 yr. Stored pollen was found potent wherever it was shown to possess good vitality in germination tests. Apple pollen which had apparently lost viability after storage in the laboratory for 5 weeks was revived by being placed in storage at from 2° to 8° and a relative humidity of 80 percent.

Low temperature injury to orchards in Pennsylvania and adjoining States in the fall and winter of 1935-36, R. D. ANTHONY, R. H. SUDDS,

and W. S. CLARKE, JR. (*Amer. Soc. Hort. Sci. Proc.*, 33 (1936), pp. 33-43, fig. 1).—The results are presented with discussion of a survey of widespread winter injury to fruit trees in Pennsylvania and adjacent areas. The greatest injury occurred in an elliptical area centering roughly around Pittsburgh and extending 50 miles north, 25 miles south, 75 miles east, and with a somewhat indefinite western border in Ohio. A heavy crop in 1935, an untimely freeze in early October which checked normal maturation, and a sudden drop in temperature in January combined to form a critical situation. Low temperature alone is not considered the primary cause, because some of the orchards had passed safely through much colder winters. In general, those tissues which are slowest to attain maturity, namely the bases of buds, large crotches, and lower limbs, were most severely injured. Both excess vigor and lack of vigor were contributing factors, while the time and amount of fertilizer applications seem to have influenced the degree of injury only as they affected the maturity of the trees.

The condition of apple trees in western Illinois following the severe winter and drouth, V. W. KELLEY (*Ill. State Hort. Soc. Trans.*, 70 (1936), pp. 456-471, figs. 9).—Following a brief discussion of the climatic conditions associated with injury, the author describes types of injury, discusses probable factors affecting injury, and presents suggestions for aiding recovery.

Soil erosion in Michigan orchards, N. L. PARTRIDGE (*Michigan Sta. Circ.* 162 (1937), pp. 35, figs. 24).—Incidental to various orchard soil management studies conducted by the station since 1920, there were collected many data and photographs relating to the prevalence and effects of soil erosion in orchards, vineyards, and other fruit plantations. In this circular there are assembled some of the more pertinent facts, accompanied by a discussion of various methods of reducing and preventing erosion losses. Erosion due to washing and blowing is said to be a serious factor in many Michigan orchards. Continuous cultivation contributes to erosion losses, while permanent sod covers are considered the cheapest and most effective method for controlling erosion. Where cultivation is required, protective strips of sod may be left in each tree row. Mulching heavily with grass or other material about the trees is also an effective substitute for cultivation. The control of erosion in orchards is of necessity a compromise between the most effective method of soil retention and the best method of soil management as related to economic production. The fact is emphasized that orchards should be established on soils which have not been subjected to serious erosion in the past.

Ringling and fruit setting as related to nitrogen and carbohydrate content of Grimes Golden apples, L. GREENE (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 11, pp. 863-875, fig. 1).—In studies by the Indiana Experiment Station, the early ringling of branches on vigorous 8-year-old trees growing under clean cultivation and cover-crop system of management resulted in an approximate doubling in the percentage of spurs that set fruit. Scoring the branch by drawing a knife blade twice around the limb without removing the enclosed bark was also effective. Ringling and scoring apparently increased the average number of fruits per spur. Ringling had relatively less effect on branches that tended to set fruit abundantly. There was a considerable period of time during and following blossoming in which ringling was influential on fruit setting. Ringling increased the weights of apple spurs, particularly the reproductive organs and the cluster base. Spurs from ringed branches were higher in sugar and starch than those from comparable nonringed branches. Sucrose was influenced less by ringling than was the content of reducing substances. Leaves from ringed branches were consistently higher in total sugars, but this did not

hold true for other spur parts. On a dry-weight percentage basis, spurs of nonringed branches had a slightly higher nitrogen content except that the fruits remained fairly constant between treatments. Carbohydrate accumulation was apparently of importance in preventing the excessive dropping of fruits.

Boric acid injections prove injurious, W. O. GLOYER (*Farm Res. [New York State Sta.], 3 (1937), No. 4, p. 14, fig. 1*).—The insertion of boric acid crystals into the trunks of 10-year-old Baldwin apple trees almost ruined the trees. Spiral streaks of dead bark were formed, and any branches in the path of the streak were killed. Varieties apparently differed somewhat in their susceptibility to boron injury. The difference between drought spot and stippen is indicated.

Three distinct stages traced in the growth of fruit, H. B. TUKEY (*Farm Res. [New York State Sta.], 3 (1937), No. 4, pp. 1, 15, fig. 1*).—The author points out that in the stone fruits, notably the peach, cherry, apricot, and plum, there are three separate and fairly characteristic periods of fruit growth: (1) A period of rapid initial development, (2) a period of delayed development, and (3) the final swell. Early-maturing varieties have relatively short periods of delayed development. The bearing of the periodic development on thinning is discussed, with the suggestion that in late-ripening peaches, such as Hill Chili, thinning may be deferred much later than in a variety like Greensboro.

The results of 50 years of breeding cherries, G. H. HOWE (*Farm Res. [New York State Sta.], 3 (1937), No. 4, pp. 3, 9*).—This the third of a series of articles (E. S. R., 77, p. 190) on new and noteworthy fruits, discusses the Seneca and Gil Peck sweet cherries originated by the station and other cherries, such as Geant d'Hedelfingen, Royal Duke, and Chase, which are considered especially well worth-while. Pollination requirements and rootstocks are briefly discussed.

New peach varieties, M. J. DORSEY (*Ill. State Hort. Soc. Trans., 70 (1936), pp. 241-247*).—In this brief paper, the more recent introductions are rated according to their hardiness and discussed in view of their potential value.

Research investigations with strawberries at Montrose, Iowa, T. J. MANLEY, B. S. PICKETT, and P. A. MINGES (*Iowa State Hort. Soc. Rpt., 70 (1935), pp. 41-44, figs. 2*).—With a view to studying varietal adaptation and response to soil treatment, an experiment was laid out by the Iowa Experiment Station near Montrose. In the spring of 1935 plats receiving stable manure or phosphorus alone were apparently more productive and superior in condition. A spring application of 800 lb. of 5-7-7 fertilizer to Dunlap plants stimulated growth and apparently increased resistance to leaf spot, but the yields were decreased in comparison to the no-fertilizer plats. The U. S. Department of Agriculture varieties—Dorsett, Fairfax, Narcissa, and Blakemore—showed up to advantage. Among everbearers, Mayzata and Mastodon were superior.

Breaking the rest period of the strawberry by long days at high temperatures, G. M. DARBOW (*Science, 85 (1937), No. 2207, pp. 391, 392*).—Observations at the U. S. D. A. Research Center, Beltsville, Md., on the responses of strawberries to differential photoperiod and temperature levels during the winter season indicated, that long days at high temperature may be fully effective in breaking the rest period. The plants were brought into the greenhouse from the field on September 1, November 15, and January 1, and measurements of leaf area were made on March 2. At 70° F. all varieties developed approximately the same leaf area under 16- and 14-hr. day lengths. Under normal days the September 1 and November 15 groups behaved similarly and were still at rest, while the January 1 group developed considerable leaf area, indicating that its rest period had been broken. At 70° and 16- and 14-hr.

day lengths the September 1 plants did not undergo any rest period, and that of the November 15 lot was broken. At 60° and 16 hr. of day, the September 1 plants did not undergo rest, but at 60° and 14 hr. the September 1 group went into a rest period and the November 15 group did not have its rest broken. The fact that the strawberry plant retains green leaves during the dormant season is said to permit light to take effect so that long days with high temperatures are effective in breaking the rest period.

Handling strawberry plants to avoid losses, M. B. HOFFMAN and J. A. EVANS (*N. Y. State Hort. Soc. Proc.*, 82 (1937), pp. 267-270).—Stating that serious losses have occurred in new plantings of strawberries received from southern sources, apparently due to winter-injured roots, the authors present the results of a study of plants obtained at different dates and handled in different ways after reception. The best results were secured with plants received March 25, held in cold storage at 31° F., and planted April 14. The poorest results were secured with plants received May 7 and set immediately in the open. The use of dormant plants set early is conceded to be a good practice, although perhaps not a complete solution of root rot troubles.

Aphis resistance in breeding mosaic-escaping red raspberries, C. D. SCHWARTZ and G. A. HUTER (*Science*, 86 (1937), No. 2224, pp. 153, 159).—Having observed that Lloyd George variety completely escaped mosaic infection in the Puyallup Valley by virtue of its resistance to the aphid vector, *Amygdalophora rubi* Kalt., and that this variety transmits resistance when crossed with susceptible kinds, careful records were made by the Washington Experiment Station on 10 red varieties in the field, with evidence that the rate of spread of mosaic appears directly proportional to the aphid populations present. In the greenhouse, aphids were unable to maintain themselves on Lloyd George. Of 31 reciprocal hybrids between Lloyd George and Cuthbert, 6 proved completely resistant and several others highly resistant. Of 6 hybrids between Lloyd George and Latham, 3 were resistant and 3 susceptible. Of 19 hybrids of susceptible parents, all were definitely susceptible. The authors believe that the failure of the aphid above mentioned to infest Lloyd George is due to a lack of suitable food in the plant rather than the presence of repellent substances.

Hastening the production of fruit in grape hybridizing work, E. SNYDER and F. N. HARMON (*Amer. Soc. Hort. Sci. Proc.*, 33 (1936), pp. 426, 427, fig. 1).—The details are presented of a method of technic, using the T bud with some modifications, whereby ripe fruits have been produced 18 mo. after the grape seeds were planted in the greenhouse flats.

Breeding hardy muscat grapes, R. WELLINGTON (*Amer. Soc. Hort. Sci. Proc.*, 33 (1936), pp. 421-425).—Stating that the Golden Muscat, introduced by the New York State Experiment Station in 1927 and possessing a distinctive muscat flavor, is very late in ripening, the author presents the results secured with various crosses in which Muscat Hamburg figured in the parentage. Of 197 seedlings which have reached the fruiting stage, 80 possessed the muscat flavor. A total of 24 were propagated, one of which is Golden Muscat. It is suggested that several hardy muscat varieties will be available in the near future.

Fruit-bud and flower formation in the Sultanina grape, A. J. WINKLER and E. M. SHEMSETTIN (*Hügaräia [California Sta.]*, 10 (1937), No. 15, pp. 589-611, pls. 5).—Studies of buds collected at different times throughout the year from vines growing in the station vineyard showed the beginning of cluster primordia formation during the first week of June. Appearing as a blunt, rather broad outgrowth of the growing point of the bud, the cluster primordium was readily distinguished from the leaf primordium which was characteristically pointed.

Observations on the fruitfulness of the buds of canes from the basal to the twentieth showed the region between the fourth and twelfth to be the most productive. The primordial clusters in the basal and apical buds were not as large as those in the middle of the canes. The development of the cluster primordia was rapid at first but with no perceptible increase during the dormant season. Bract formation, the first indication of the division of the primordial cluster, was discernible in from 7 to 10 days after cluster initiation. Tendril primordia formed later in the season than did cluster primordia. Flower development was regular, and the development of the parts was complete in from 6 to 7 weeks after leafing out.

Fruit bud studies.—III, The Sultana: Some relations between shoot growth, chemical composition, fruit bud formation, and yield, J. E. THOMAS and C. BARNARD (*Jour. Council Sci. and Indus. Res. [Austral.]*, 10 (1937), No. 2, pp. 148-157, figs. 2).—In this third contribution (E. S. R., 70, p. 780) there are discussed some of the relations between shoot growth, accumulation of starch and nitrogen, the current and succeeding crops, and fruit bud formation in the Sultana grape. In vineyards of subaverage to average vigor the more vegetative vines tended to be more productive, whereas in vineyards of vigorous growth no significant correlation was observed between vigor and yield of individual vines. Bud fertility was significantly and positively associated with diameter and weight but not with mean internode length of the canes. A close correlation was noted between the percentage of starch in the annual wood and fruit bud formation. The presence of a heavy crop was one of the most important factors depressing shoot growth, starch accumulation, and fruit bud formation.

The future of bud selection, R. E. CARYL (*Calif. Citrogr.*, 22 (1937), No. 7, pp. 289, 328-330, figs. 3).—Stating that there are a great many strains and variations of oranges, grapefruit, and lemons growing at the Citrus Experiment Station, the author suggests a general survey of the bud selection situation in citrus, pointing out that selection has a very important function in the development of vigorous productive trees yielding high-quality fruit. Such characters as thorns may be eliminated, minor variations removed, and the quality generally improved.

Frost injury to bearing orange trees, A. D. SHAMEL (*Calif. Citrogr.*, 22 (1937), No. 7, pp. 290, 307, figs. 2).—Following the disastrous freeze of 1913 and the less severe one of 1922, the author observed that the immediate pruning of orange trees or that performed shortly afterwards actually was detrimental to recovery and retarded a return to fruiting condition by one or more seasons. Whitewashing the exposed bark delayed the development of adventitious buds a week or so, but was distinctly helpful in reducing sunburn. An early application of reasonable amounts of nitrogen was evidently helpful in recovery. No benefit was seen from binding injured trunks or main limbs unless done immediately after the injury.

Nitrogen fertilization and root aeration, A. R. C. HAAS (*Calif. Citrogr.*, 22 (1937), No. 7, pp. 286, 332, 333, figs. 3).—At the Citrus Experiment Station, Riverside, Calif., rooted leafy-twig cuttings of lemon planted January 29 in soil the nitrogen fertilizer for which was supplied from various sources made the quickest and best growth with sulfate of ammonia. In solution cultures, lemons grown with potassium nitrate or calcium nitrate were very tardy in making a new top growth as compared with plants receiving other forms of nitrogen, such as magnesium or sodium nitrate. Nitrate nitrogen when combined with a suitable base gave excellent results. When nitrate became deficient in a culture solution, the roots became gelatinous and dark in color

and gave off a strong odor of decomposition. The addition of calcium nitrate without aeration resulted in a few days in the renewal of root development. The author suggests that the nitrate may be able to supply oxygen for the healthy development of the roots. In the presence of continual aeration, the lack of nitrogen did not result in breakdown or bad odor.

Cold storage tests of grapefruit and oranges, J. F. WOOD, W. H. FRIEND, and G. H. GODFREY (*Tex. Farming and Citric*, 14 (1937), No. 2, p. 7).—Comparisons made by the Texas Experiment Station of 34° and 44° F. for the storage of citrus fruit indicated that with the grapefruit the higher temperature is somewhat preferable, but the results were not favorable at either point. The Marsh grapefruit held up better at 34° than did the Little River. Of different washes used on the Foster Pink grapefruit, a soap wash gave the best results. Valencia oranges stored at 34° and 44° kept 100 percent and 99+ percent sound, respectively, from March 18 to May 10, and treatment with the various washes had no marked effect. Aluminum foil and cellophane wraps kept oranges in perfect condition, as compared with about 90 percent sound with the controls. The lining of boxes with wrapping paper of various kinds improved the keeping of Valencia oranges.

Morphology of the flower and fruit of the loquat, R. M. SMOCK (*Hortgardia [California Sta.]*, 10 (1937), No. 15, pp. 613-632, pls. 4, figs. 5).—The examination of buds, flowers, and fruits collected at Davis at weekly intervals during the season from a tree of the Advance variety showed an extended period of flower bud differentiation and of flowering. The first discernible sign of flower-bud differentiation was a distinct, blunt protuberance. In the development of the macrogametophyte, the macrospore mother cell underwent heterotypic and then homeotypic division, resulting in the formation of a tetrad of macrospores. The loquat possessed 10 ovules, but only one or occasionally two seeds developed in each fruit despite the fact that apparently normal macrogametophytes were formed in all ovules.

Vascular anatomy resembled that of the apple with certain characteristic differences, e. g., the region of anastomosis in the stele of the pedicel was less extended than in the apple. The fruits had a hood or cap of toral tissue enclosing the distal portion of the ovary. The functional seed or seeds were fertile and occupied the whole central region of the fruit. The development of the seeds resulted in a marked distortion of the carpel walls and a complete disintegration of the nonfunctional ovules and the carpels in which they were located.

Differences in heterosis of walnut hybrids, C. E. SCHUSTER (*Jour. Heredity*, 28 (1937), No. 6, pp. 216, 217).—Observations on two populations of hybrid walnuts, both with the same mother parent, the Franquette variety of *Juglans regia* L., but one with Stabler as pollen parent and the other with a tree of *J. nigra*, showed material differences in growth. The Franquette × Stabler seedlings were vigorous, while those of the other lot were weak. In 1936 the Franquette × Stabler seedlings made a foot or more of new growth before the others had even opened their buds.

Flowering crab-apples, G. P. VAN ESELTINE (*Penn. Univ., Morris Arboretum Bul.*, 1 (1937), No. 8, pp. 103-105).—Information is presented as to methods of producing hybrids, general culture, and the value of existing species and varieties.

FORESTRY

Studies in tolerance of New England forest trees.—XIII, The effect of root development on height and diameter growth, G. P. BURNS (*Vermont*

Sta. Bul. 422 (1937), pp. 29, figs. 10).—In continuation of this series (E. S. R., 73, p. 788), trees developed from seed taken from a single cone of cypress, *Taxodium distichum*, were grown in the greenhouse in three different soil environments representing pond, swamp, and land conditions. At the end of 3 yr. the trees were cut, and striking differences were observed in height, trunk diameters, root and branch development, and foliage. On an oven-dry basis the pond, swamp, and land trees weighed 908.6, 370.3, and 152.5 g, respectively. The roots weighed 278.5, 208.3, and 80.1 g, respectively. There were no fibrous roots on the land tree. Specific gravity determinations of the wood in the basal sections of the trunks gave 0.306, 0.383, and 0.581 for the pond, swamp, and land trees, respectively. The greatest difference in increment of trunk occurred in the third year following the development of adventitious roots on the pond tree. Annual rings were more pronounced and regular in the land tree. Measurements of the cells in the basal sections of the trunks showed the land tree to have cells with the smallest radial diameters, the pond tree the largest, and the swamp tree intermediate. The root system of the pond tree was approximately three times as efficient in the production of dry weight as were those of the other two trees. The leaves of the swamp tree were most efficient both in volume and dry weight production, suggesting that the pond tree, despite its larger root system, was not able to absorb enough minerals to permit the tree to use effectively the carbohydrates produced. The author concludes that any attempt to evaluate the effect of site on the amount of increment produced by forest trees during a definite period must be based upon a physiological summation of all the site factors.

Relation of size of deciduous nursery stock to field survival in the Great Plains, J. H. STOECKELER (*Jour. Forestry*, 35 (1937), No. 8, pp. 773-777, figs. 4).—Tests conducted in the winter of 1935-36 near Mangum, Okla., with 1-year-old seedlings of 14 species, all taken from nurseries in the west-central part of the State, showed that relatively large planting stock survives best. Stock with a caliper of $\frac{3}{8}$ to $1\frac{1}{8}$ in. at 2 in. above the soil is considered best for windbreak planting in the Great Plains area when both survival and the cost of planting are considered. Nursery-grown stock usually gave better survival than did seedlings obtained along the streams. Grading standards required modification according to the growing habit of the species.

Commercial planting on redwood cut-over lands, H. L. PEARSON (*U. S. Dept. Agr. Circ. 434 (1937), pp. 40, figs. 15*).—Following the virtual collapse of a large commercial redwood planting project in Humboldt and Mendocino Counties, Calif., a study was made of survival, possible causes of success and failure of plantings, etc. The commercial project continued over the years 1922-32, during which time there were planted by 10 companies over 12,000,000 trees on 26,400 acres at an approximate cost of \$234,000. Redwood was the principal species planted, with Douglas fir, Port Orford cedar, and Sitka spruce making up the balance. Based on observations on established sample plats, there were found survivals of 32 percent and 41 percent in Humboldt and Mendocino Counties, respectively. Port Orford cedar and 2-yr. redwood transplants showed up to the best advantage. Survival on steep southerly exposures was particularly poor. Height growth was generally poor, with 6-yr. planted trees averaging barely 3 ft.

The time elapsing between logging and planting was found of major importance, and plants set within 1 yr. after logging showed more than twice the survival of those planted 2 yr. or more later. Less rodent damage on the newly logged areas was apparently the major factor in this difference. In conclusion, it is suggested that fairly successful planting is possible at moderate cost if

newly logged areas are promptly planted with sturdy stock. It is believed that the poor height growth and poor survival record may have been due in a considerable part to site deterioration resulting from heavy postlogging fires and subsequent erosion.

Storage and dewinging of American elm seed, E. J. GEORGE (*Jour. Forestry*, 35 (1937), No. 8, pp. 769-772).—Thoroughly ripened and dried seeds were kept successfully over a 1-yr. period when stored either in the open or in closed containers. The temperature range during the year was from 115° to -28° F. The seed was successfully dewinged to permit machine sowing. Storage for a year permitted planting elm seed in the spring when the soil was moist and conditions were favorable, and spring planting resulted in the growing of suitable-sized stock in a single season.

Root studies of important range plants of the Boise River watershed, L. E. SPENCE (*Jour. Forestry*, 35 (1937), No. 8, pp. 747-754, fig. 1).—Because of the serious range erosion situation, a study was made of the root systems of the principal herbaceous plants of an important range watershed area on the Boise River. The roots of 500 species were divided into four classes—(1) fibrous, (2) semifibrous, (3) semitaproot, and (4) taproot. The results indicated that the erosion problem on the area in question was largely the result of replacement of fibrous rooted species by those of the taproot and semitaproot classes. The surface soil or virgin range land was filled with a dense mass of roots which effectively controlled erosion.

Harvesting and marketing timber in New York, R. J. HOYLE (*N. Y. State Col. Forestry, Syracuse Univ., Bul.*, 9 (1936), No. 2-a, pp. 186, figs. 59).—This is a general discussion on the harvesting of trees and forests and the preparation of the rough products into form for use in further manufacture.

A board foot volume table for eastern red cedar, W. MAUGHAN (*Jour. Forestry*, 35 (1937), No. 8, pp. 734, 735).—Supplementing the data used in preparing a volume table (E. S. R., 76, p. 45) with additional measurements, there is now presented a board foot volume table for the red cedar.

Tree-fork and steel tape for close measurement of small diameters, W. H. CUMMINGS (*Jour. Forestry*, 35 (1937), No. 7, pp. 654-660, figs. 3).—The author describes a modified steel tape and tree-fork developed for the rapid, close diameter measurement of stems between 0.02 and 10 in. For stems larger than 10 in. the tape vernier readings are, in general, of no significance.

The technique of duff hygrometer calibration, T. KACHIN and H. T. GIBBORNE (*Jour. Forestry*, 35 (1937), No. 8, pp. 736-743, figs. 2).—Discussing the use of the hygrometer and the necessity for accuracy, the authors present information on the technic of calibration.

Fire Control Notes, August 9, 1937 (*U. S. Dept. Agr., Forest Serv., Fire Control Notes*, [No. 5] (1937), pp. 229-304, figs. 13).—In the usual manner (E. S. R., 77, p. 492), brief papers are presented on various phases of fire control and fire prevention activities.

DISEASES OF PLANTS

Introduction to research on plant diseases: A guide to the principles and practice for studying various plant-disease problems, A. J. and R. S. RIKER ([*Madison, Wis.*]: *Authors*, 1936, pp. [1]+III+117, figs. 19).—"This collection of methods has been prepared primarily as an introduction to research for the use of students interested in plant diseases." Following a section on preliminary considerations, the subject matter is considered under the following chapter headings: Foundation of a research problem; general laboratory

equipment; culture media; certain physical-chemical measurements; isolation, culture, and inoculation; virus diseases; certain procedures for pathological histology; epidemiology, environment, and control; statistical analyses; records and manuscripts; and laboratory exercise topics.

Literature references are given at the end of chapters. Eight tables and an index are included.

Phytopathogenic bacteria: Bacteria causing diseases of plants, G. K. BUREVITS (*Fitopatogennye bakterii: Bakterii vzbuditeli boleznei rastenii. Leningrad: Akad. Nauk. S. S. R., 1935, pp. 252*).—This is a manual of phytopathogenic bacteria covering 10 species of *Bacillus* and 174 of *Bacterium*, with their synonymy and including many new combinations to conform with the nomenclatorial system used by the author. Alphabetical indexes of the bacterial parasites and hosts and an index of the hosts (with a list of bacterial parasites for each) by their systematic groupings are provided.

A staining and maceration method of tracing the path of the vascular bundles in herbaceous plants, and its application in observations on the distribution of *Bacterium solanacearum* in relation to epinastic curvatures in petioles of tomato and potato plants, B. J. GRIEVE (*Roy. Soc. Victoria, Proc., n. ser., 49 (1936), No. 1, pp. 72-75, pl. 1*).—The stems are severed at the base and the plants held in 1 percent solutions of eosin or basic fuchsin until the dye has reached the topmost leaves (1-2 hr.). The epidermis is then slit along the stems and petiole bases and the plants are immersed in 15 percent nitric acid previously raised to the boiling point until sufficiently flaccid for dissection (a few seconds to 5 min.), washed in running water for 10 min., and allowed to stand in water overnight. The epidermal and cortical tissues are then dissected away with fine pointed forceps, whereupon the red dyes afford a visual and photographic color contrast with the bacterially filled vascular bundles. The method proved especially useful in anatomical work on herbaceous plants, in large measure obviating the laborious serial sanctioning method.

Serological reactions for the determination of bacterial plant pathogens, W. H. BURKHOLDER (*Phytopathology, 27 (1937), No. 4, pp. 572-574*).—Based on a critical discussion and review of work in this field, it is concluded in this contribution by Cornell University that until careful and extensive work has been conducted on the serology of the bacterial plant pathogens too much emphasis should not be placed on individual reactions.

The distribution of *Fusaria* in nature, H. W. WOLLENWEBER and O. A. REINKING (*Die Verbreitung der Fusarien in der Natur. Berlin: R. Friedlander & Son, 1935, pp. 80, figs. 41*).—This monograph includes lists of the *Fusaria* and related ascus forms, with references to the illustrations of these fungi in "*Fusaria autographica delineata*"; the *Fusaria* arranged according to taxonomic groups and subgroups, with their related ascus forms; the occurrence of *Fusaria* on plants (including fungi), animal organisms, and crude materials and products of plant and animal origin, and in the soil, air, and water; host plants, with the *Fusarium* species reported on each; *Fusaria* reported on blue-green and green algae, lichens, and mosses; the *Fusarium* flora of other fungi; and other fungus genera which frequently have been confused with *Fusarium*, together with illustrations of conidia of 12 such genera.

A simple and rapid method for identifying plant viruses in the field, K. S. CHESTER (*Phytopathology, 27 (1937), No. 6, pp. 722-727, fig. 1*).—A method is described whereby fresh, green leaf juice may be tested for the presence of virus by mixing it with serum in the field. The reaction appears to be an agglutination of the suspended plastids in the juice. A given virus juice will

react only with the type of serum specific for that virus. The method is inexpensive and very little equipment is required. On the average, the reactions appear in 10-20 min. The method has proved successful with six viruses of tobacco and appears to be somewhat more sensitive than the customary laboratory technics for serological identification of viruses.

The intracellular crystallization of Stanley's tobacco virus proteins, H. P. BEALE (*Jour. Bact.*, 33 (1937), No. 3, pp. 536, 537).—An abstract.

Insect transmission of virus diseases of plants, M. T. COOK (*Sci. Mo.*, 44 (1937), No. 2, pp. 174-177).—This general review is a contribution from the Puerto Rico Experiment Station.

The need of permanent reference collections of insect vectors of plant diseases, F. F. SMITH (*Phytopathology*, 27 (1937), No. 2, pp. 198-202).—In some cases viruses are most readily identified by their vectors. Closely related insect species are also known to transmit entirely different viruses, and reference is made to several cases regarding confusion in the identity of a given vector and its effects on the results of studies of the diseases concerned. Because of the lack of agreement relative to the specificity of certain known insects and because new species are not always readily differentiated by descriptive literature alone, it is suggested that representatives of bona fide insect vectors of plant viruses be permanently preserved in designated institutions.

Uniformity and stability of mycological nomenclature, C. L. SHELAR (*Mycologia*, 28 (1936), No. 4, pp. 337-346).—This is a historical account, a discussion of the difficulties and principles involved, and a presentation of certain practical suggestions relative to fungus nomenclature.

The scientific principles of plant protection, with special reference to chemical control, H. MARTIN (London: Edward Arnold & Co., 1936, 2. ed., pp. XII+379).—The first edition has been previously noted (*E. S. R.*, 68, p. 626). In this edition "the inclusion of new material has necessitated a drastic revision, and, except for the introductory chapter, the book has been rewritten."

Recent developments in fungicides: Spray materials, J. W. ROBERTS (*Bot. Rev.*, 2 (1936), No. 12, pp. 586-600).—This is a general discussion of the sulfur, copper, and other types of fungicides and of additives used to improve spreading and sticking qualities. One hundred and two references are cited.

Progress in plant pathology: Control of disease by resistant varieties, G. H. COONS (*Phytopathology*, 27 (1937), No. 5, pp. 622-632, fig. 1).—Disease-resistant varieties are estimated to occupy approximately one-quarter of the area devoted to 17 leading crop plants and to contribute from 60 to 70 million dollars annually to farm values. The principles underlying disease-resistance breeding and the nature of disease resistance are briefly outlined.

Recent fluctuations in plant diseases in the United States, N. E. STEVENS and J. I. WOOD (*Bot. Rev.*, 3 (1937), No. 6, pp. 277-306, figs. 18).—"It is the purpose of the present review [including 17 literature references] to bring together the available information regarding the extent of the fluctuations of certain diseases in the United States prior to 1936." The following subjects are considered: Crop loss estimates compiled by the Plant Disease Survey, tobacco downy mildew, bacterial wilt of corn and the losses suffered by sweet corn, losses due to corn ear rots, losses from stem rust of wheat, storage rots of sweetpotato, peach brown rot, apple scab, sugar beet curly top, losses from cranberry fruit rots and what is meant by "good" keeping quality, and attempts to appraise the economic effects of fluctuations in plant diseases.

The Plant Disease Reporter, August 1 and August 15, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 21 (1937), Nos. 14, pp. 259-280,

figs. 10; 15, pp. 281-294, figs. 2).—Among other items of current interest, these issues contain the following notes:

No. 11.—January temperatures in relation to the distribution and severity of downy mildew (*Peronospora tabacina*) of tobacco, by P. R. Miller; peach cankers, by E. M. Hildebrand and W. D. Mills; extent of *Botrytis* rot in a strawberry field following frosts and rains, by G. M. Darrow, E. B. Morrow, G. A. Meckstroth, and C. Dearing; fruit disease eradication activities (including citrus canker and peach mosaic disease); additional breeding areas of beet leafhopper found in Texas; potato disease survey in Oklahoma, by T. B. Gordon; losses from potato diseases in northern Florida, 1932-37, by A. H. Eldins; additional notes on downy mildew (*Peronospora destructor*) and other diseases of onion in New York; wheat stem rust in Minnesota and North and South Dakota, by E. C. Stakman; plant diseases reported in Ohio, by A. L. Pierstorff; white pine blister rust (including data on its spread, pine-infection surveys, and phenological data); Dutch elm disease eradication notes; and diseases of trees observed this year in New Jersey, by R. P. White.

No. 15.—Two fungus diseases (*Fusarium conglutinans* and *Verticillium albo-atrum*) of vegetables new to Florida, by G. F. Weber; vegetable diseases in northern Ohio in 1937, by J. D. Wilson; downy mildew and blast of onion in Massachusetts and New York, by O. C. Boyd and A. G. Newhall, respectively; miscellaneous notes on vegetable diseases in Massachusetts, by O. C. Boyd; reports on fruit diseases, including apple scab (*Venturia inaequalis*) in Massachusetts and in New York, and strawberry dwarf in Massachusetts; downy mildew and other diseases of tobacco in Massachusetts, by O. C. Boyd; bacterial diseases of tobacco in Canada, by L. H. Koch; leaf blister (*Taphrina coerulescens*) or curl of oak, by O. P. Owens; and Dutch elm disease eradication notes.

Plant pathology (*Idaho Sta. Bul. 221 (1937), pp. 8, 38-42, 48, figs. 2).*—Progress reports are included on tests of mosaic-resistant beans for resistance to curly top disease; new small red beans resistant to diseases; Norida, a new small white bean, developed; Idaho Refugee proves to be of good canning and freezing quality; mosaic diseases and *Fusarium* wilts of peas; potato seedling tests for virus disease resistance; and fruit disease investigations initiated, all reported by C. W. Hungerford. J. Toews reports the results of seed treatments for control of spring wheat bunt, and H. P. Magnuson on the control of chlorosis in apples and grapes.

[Plant disease work by the Kentucky Station] (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 27-33, 35, 36, 47).*—Progress reports are given on two new stalk diseases of tobacco (*Rhizoctonia* and a bacterial phloem necrosis), tobacco black shank, blue mold, mosaic (including overwintering in diseased roots, stalks, and leaves, and thermal and trisodium phosphate inactivation of the virus), root rot resistant varieties of tobacco, *Fusarium* wilt of White Burley tobacco, overwintering of bacterial leaf spots of tobacco, nature of the toxin of *Bacterium tabacum* [= *Phytophthora tabaci*], variations in pathogenicity of *B. tabacum* and *B. angulatum* [= *P. angulata*], bordeaux spray tests against these two pathogens of tobacco, the relation of soil productivity and diseases to red clover failure, and the status of phony peach.

[Plant disease work by the Massachusetts Station] (*Massachusetts Sta. Bul. 339 (1937), pp. 14-18, 25-31, 32).*—Progress reports are given on black root rot of tobacco, by C. V. Kightlinger; control of greenhouse tomato diseases, by E. F. Guba; causes and control of decay of winter squash in storage, by Guba and C. J. Gilgut; vegetable seed treatments, tests of fungicides on field tomatoes, *Verticillium* wilt of eggplant, spraying greenhouse cucumbers

for control of powdery mildew, and trials of so-called rust-resistant beans, all by Gilgut and Guba; carnation blight, *Alternaria dianthi*, by Guba; diseases of herbaceous ornamental plants caused by soil-infesting fungi, and damping-off and growth of seedlings and cuttings of woody plants as affected by soil treatments and modifications in environment, both by W. L. Doran; elm diseases in Massachusetts, by M. A. McKenzie and A. V. Osmun; Selocide spray as a plant stimulant, by F. F. Bobula and L. H. Jones; and the effect of soil temperature on a chlorosis of gardenia, by Jones.

[Plant disease work by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1935*, pp. 22-40).—Under the annual report of the plant pathologist for the fiscal year 1934-35, M. T. Cook summarizes the work of the division, including progress reports on root diseases of sugarcane, mosaic diseases, and rind disease of sugarcane; breeding for resistance to diseases (including tomato wilt and bacterial wilt of eggplant), by A. Roque; and plant disease survey data relative to various specific crop plants.

Under the annual report of the assistant phytopathologist, Roque gives progress reports on studies of tomato wilt disease due to *Bacillus solanacearum* [= *Phytophthora solanacearum*], tobacco mosaic, cucumber mildew control, control of bacterial wilt of eggplants due to *B. solanacearum*, diseases of minor crops, *Alternaria* spot of cotton, yam wilt associated with a *Fusarium*, fruit rot of cucumbers due to *Pythium aphanidermatum*, black tip of bananas (plantains) due to *Helminthosporium torulosum*, onion blight and pink root, avocado wilt associated with a *Fusarium*, and eggplant fruit rot associated with a *Pythium*.

[Plant disease work by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1936]*, pp. 28, 29, 31, 32).—Progress reports are given on spray injury to tomatoes, and on turf disease control (including brown patch, dollar spot, and pink patch).

Gall formation in host plants following haustorial invasion by *Cuscuta*, H. L. DEAN (*Amer. Jour. Bot.*, 24 (1937), No. 3, pp. 167-173, figs. 23).—The author describes gall formation induced in nature and experimentally on 23 species of plants by 5 species and 1 variety of *Cuscuta*.

Spore formation and discharge in *Fomes fomentarius*, H. MEYER (*Phytopathology*, 26 (1936), No. 12, pp. 1155, 1156).—Data are presented on the duration of spore discharge (about 1 mo.) and on the total weight and number (approximately 7,563,493,150) discharged from the fruiting body under laboratory conditions. Culture and germination tests are briefly noted.

The persistence of *Hypholoma incertum* about tree stumps, F. C. STEWART (*Mycologia*, 28 (1936), No. 5, pp. 445-450).—This is a contribution by the New York State Experiment Station.

Comparative studies on cultures of *Phytophthora lactucae-scariorum* n. sp. and *Phytophthora pruni*, H. H. THORNBERRY and H. W. ANDERSON (*Phytopathology*, 27 (1937), No. 1, pp. 109, 110).—*P. lactucae-scariorum* is the name proposed for an organism pathogenic to leaf tissues of wild lettuce (*Lactuca scariola*), but which is nonpathogenic to cultivated lettuce and the foliage or green shoots of peach. Its morphological and cultural characteristics, as given in the technical description, are indistinguishable from *P. pruni*.

Antagonistic action of *Trichoderma* on *Actinomyces scabies* and *Rhizoctonia solani*, R. H. DAINES (*Amer. Potato Jour.*, 14 (1937), No. 3, pp. 85-93).—*T. lignorum* was found in this study from the New Jersey Experiment Stations to produce a diffusible principle toxic to *A. scabies*, as well as to *R. solani*. However, due to the fact that this principle is rapidly destroyed by aeration at the pH of potato soils and is removed from solution by charcoal and

destroyed or removed from solution by the soil itself, it appears doubtful that this fungus will prove of much assistance in controlling potato scab. A soil bacterium was also found which produces a substance toxic to both *Trichoderma* and *Actinomyces*. "Organisms which show a similar inhibiting action to these organisms in artificial media are probably numerous. However, in such complex physical, chemical, and biological environments as are afforded by soils these antagonistic relationships may be modified or even entirely destroyed."

A comparison of the effects of tellurium and selenium on plants and animals, A. L. MARTIN (*Amer. Jour. Bot.*, 24 (1937), No. 4, pp. 198-203, figs. 3).—The toxicity of tellurium to wheat plants was found proportional to the concentration added as potassium tellurite to culture solutions. Low concentrations reduced growth and induced a yellow-white mottling of the leaves, while higher concentrations caused complete drying of the leaves and reduction in size of the secondary roots. Still higher concentrations prevented the unrolling of the leaves and the formation of secondary roots. Selenium was more toxic than equivalent concentrations (in parts per million) of tellurium, the most conspicuous symptom of poisoning being a "snow-white" chlorosis of the leaves.

No antagonism between tellurium and sulfur was shown. Addition of sulfur to various tellurium culture solutions increased the injury to wheat, while its addition to low concentrations of selenium in culture solutions reduced it.

Except for stunting, no injury to rats could be detected when their diet contained ground stems, leaves, and seeds of buckwheat grown on soil to which 32 p. p. m. of tellurium had been added. Early death resulted from similar tests with selenium.

Preliminary investigations on the effect of excessive soil salinity on the incidence of cereal root rots, J. E. MACHACEK (*Sci. Agr.*, 17 (1936), No. 4, pp. 215-224; *Fr. abs.*, p. 224).—Common root rot of cereals, due to *Fusarium* and *Helminthosporium* species, is reported to be widespread in Manitoba and to be intensified in soils containing considerable amounts of soluble salts. On such soils the plants remain dwarfed, the basal leaves shrivel, and tillering is reduced. Death usually occurs unless rain water carries the excess soluble salts below the region of the root crowns.

Laboratory tests have shown both these fungi capable of comparatively good growth on media containing concentrations of $MgSO_4$ sufficient to prevent seed germination in wheat and barley. Sand-culture tests and experiments with leached soil containing different amounts of $MgSO_4$ have further demonstrated the tolerance of these fungi to this salt. The study has also indicated that high concentrations of the salt retard seedling growth and increase the severity of the root rot.

Cereal rust losses in western Canada, F. J. GREANEY (*Sci. Agr.*, 16 (1936), No. 11, pp. 608-614; *Fr. abs.*, p. 614).—On the basis of controlled experiments it is estimated that during an 11-yr. period (1925-35) 10.8 percent of the possible wheat yield in Manitoba and Saskatchewan was lost annually due to stem rust. Another important source of loss from rust was the reduction in grain quality. Detailed estimates are presented.

Environmental conditions and the wasting disease of eel-grass, N. E. STEVENS (*Science*, 84 (1936), No. 2169, pp. 87-89, fig. 1).—This contribution from the University of Illinois points out that the wasting of eelgrass is not an isolated phenomenon, but that its coincidence in time with the unprecedented northward extension of bacterial wilt of corn (correlated with weather conditions) led the author to the present study. It is noted that the three known

records of wasting disease have coincided with extreme north declination of the moon (1894, 1912, and 1930), which in turn is correlated with transgressions in the Atlantic Ocean currents known to affect fisheries. In view of these facts it is believed worth-while to study the biology of eelgrass in relation to its environment through the next decade or more, and especially during the next period of wasting, which is apparently due about 1949 or 1950.

The relation of ear rot prevalence in Illinois corn fields to ear coverage by husks, G. H. BOEWE (*Ill. Nat. Hist. Survey, Biol. Notes No. 6* (1936), pp. 19, figs. 2).—During the 5 yr. from 1931 to 1935, 57,395 ears were examined in 257 fields in all parts of Illinois. A large proportion of ears (from 53 to 70 percent) was found incompletely covered by the husks. The amount of visible *Fusarium* ear rot ranged from 22 to 80.6 percent (average 40.7), partially exposed ears being on the average twice as often diseased as those fully covered. *Penicillium* was visible in from 2.3 to 11.5 percent of the ears, attack being consistently greater in partially exposed than in fully covered ears. The percentage of *Rhizopus* observed ranged from 1 to 6.8. The 5-year average for *Diplodia*, *Gibberella*, *Basisporium*, and *Aspergillus* ranged from 1.2 to 0.23 percent, respectively. Except in the cases of *Fusarium* and *Penicillium*, no consistent relation to ear coverage could, in general, be established.

Contribution to the knowledge of the *Fusarium* diseases of rye [trans. title], J. ANLIKER (*Beitr. Kryptogamenflora Schweiz*, 8 (1935), No. 4, pp. [4] + 115, pls. 3, figs. 23).—This monograph on the diseases of rye due to *F. herbaram* and *F. nivale* reports the results of isolation studies, field experiments, and pot infection tests. A bibliography of 63 titles is included.

Cytological observations on sexuality and development in *Tilletia tritici* [trans. title], WEN-YU YEN (*Compt. Rend. Soc. Biol. [Paris]*, 121 (1936), No. 13, pp. 1304-1306, figs. 14).—The author relates the anastomoses taking place among the sporidia to sexual conjugation.

A foliage yellowing and floral injury of alfalfa associated with heat and drought, F. R. JONES (*Phytopathology*, 27 (1937), No. 6, pp. 729, 730).—This cooperative contribution by the U. S. D. A. Bureau of Plant Industry and the Wisconsin Experiment Station describes the pathological conditions of alfalfa stated in the title and observed in Wisconsin in 1936 during exceptional heat and drought.

A yellowing of alfalfa due to boron deficiency, H. R. McLARTY, J. C. WILCOX, and C. G. WOODBRIDGE (*Sci. Agr.*, 17 (1937), No. 8, pp. 515-517; *Fr. abs.*, p. 517).—A distinctive type of alfalfa yellowing common in the interior of British Columbia is described. Small applications of boric acid or borax to the soil were found to remedy the trouble, while larger dosages produced injury. The boron content of the yellowed plants was consistently lower than that of the normal green plants.

The possibility of insect transmission of alfalfa dwarf, J. L. WEIMER (*Phytopathology*, 27 (1937), No. 6, pp. 697-702).—In this study by the California Experiment Station and the U. S. D. A. Bureau of Plant Industry, the spread of dwarf from diseased to healthy alfalfa plants in the field and in experimental plats suggested the possibility of insect transmission. The fact that caged alfalfa plants growing near infected plants did not become dwarfed, while uncaged plants became affected, also pointed to insects as the agents of transmission. However, the several insect species tested failed to transmit the disease to healthy alfalfa under the experimental conditions.

Cotton root-rot and weeds in native hay meadows of central Texas, C. H. ROGERS (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 10, pp. 820-823; *abs. in Texas Sta. Circ.* 79 (1937), p. 25).—Through this investigation by the Texas

Experiment Station, "the root rot fungus *Phymatotrichum omnivorum* has repeatedly been found infecting and killing plants in undisturbed Texas Blackland prairies. Sclerotia . . . of extremely high viability were found at 1-, 2-, and 8-ft. depths in the soil in an undisturbed meadow. Of a total of 47 plant species present in the meadow, 37 were susceptible to a greater or lesser degree to the root rot fungus. Additional susceptible plants were found in nearby meadows and in other meadows in other parts of the Blackland belt.

"Meadows and pastures should be kept free of weeds, not only to starve out the root rot fungus but also to produce a hay of better quality and to secure a thorough covering of grass for better combating soil erosion."

Pythium root rot of milo, C. ELLIOTT, L. E. MELCHERS, C. L. LEFEBVRE, and F. A. WAGNER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 11, pp. 797-834, figs. 22).—This is a cooperative study by the U. S. D. A. Bureau of Plant Industry and the Kansas Experiment Station.

Root rot of milo, due to *P. arrhenomanes*, first attracted attention in small experimental plats in Kansas and Texas. During the past 10 yr. it has become increasingly destructive, occurring in widely separated areas in Kansas, Texas, Oklahoma, and New Mexico. Rotting of the smaller roots results in stunting and yellowing of the plants, which die without producing heads. The pathogen occurs in the soil and has not been destroyed by ordinary rotations or fallow. It may be destroyed by soil treatments with steam, formaldehyde, and acetic acid. The development of resistant strains is the only practical method for field control. Resistant selections of Dwarf Yellow milo, Beaver, Day milo, and Wheatland have been made, and they have maintained their resistance during several years' tests. They develop normally on infested soil where ordinary Dwarf Yellow milo, Beaver, Day Milo, and Wheatland are a complete loss.

Bacterial wilt and rot of potatoes, D. B. O. SAVILE and H. N. RACICOT (*Sci. Agr.*, 17 (1937), No. 8, pp. 518-522, pl. 1; *Fr. abs.*, p. 523).—This disease entity has been observed in Quebec since 1931, and it is believed to be present in other parts of eastern Canada and the United States. Affected plants usually wilt in August, and the tubers show a discoloration of the vascular ring and become completely rotted. A slow-growing bacterium, capable of reproducing the disease and of inducing a similar condition in tomatoes, was isolated but has not yet been named.

A method of making smear preparations of the organism from diseased plants in the field is outlined in the hope that it will enable early and positive diagnosis of the disease to be made.

The susceptibility of potatoes to the vein-banding virus, L. K. JONES and C. L. VINCENT (*Jour. Agr. Res. [U. S.]*, 55 (1937), No. 1, pp. 69-79, figs. 5).—Field and greenhouse tests by the Washington Experiment Station with progeny of a single virus-free Early Rose tuber, seedling clones, and 9 commercial potato varieties showed that marked variations in symptoms are induced by infection with the vein-banding virus. Tests with seedlings developed from crossing and selfing 11 varieties indicated that only the Katahdin variety transmits resistance to this virus. Chippewa, Green Mountain, Katahdin, and Russet Burbank showed some resistance as compared with the very susceptible Bliss Triumph, Early Rose, Gold Coin, Irish Cobbler, and Warba.

Studies on *Rhizoctonia solani* Kühn.—I, Effect of potato tuber treatment on stem infection six weeks after planting, G. B. SANFORD (*Sci. Agr.*, 17 (1936), No. 4, pp. 225-234; *Fr. abs.*, p. 234).—"The effects of treating potato tubers with mercuric chloride solution, acidified, and the transfer of *R. solani* to the stems from clean treated tubers v. untreated tubers heavily infested

with sclerotia was studied under a wide range of field conditions, which included different crop sequences, culture, and soil types. The effect, as indicated on the stems 42 days after planting, was recorded by a numerical rating for severity of lesions and also by the percentage of plants without lesions. In 24 out of a total of 34 experiments (70 percent) the severity of infection was significantly greater on the plants from untreated sets heavily infested with sclerotia than on those from clean treated sets. On the basis of percentage of plants with clean stems, in 31 experiments, or 91 percent of them, an effective treatment would have been valuable at this stage. There was a tendency for increased infection arising from apparently clean untreated sets. All soils, regardless of whether the previous crop was summer fallow, cereals, truck, or potatoes, or whether of glacial origin or the black prairie loam type, carried a basic, although variable infestation. In the 34 experiments an average of 28.7 percent of the stems of plants from sets with a heavy infestation of sclerotia had lesions attributable to the sclerotia, and if the amount for which the soil infestation was responsible is included the average was only 42 percent. Extreme variability, which could not be accounted for in the transfer of the pathogen to the stems from heavily infested sets, was common during the 3 yr. of the test. The treatment used apparently caused as many missing hills as the pathogen from the sclerotia did, which average per experiment was approximately 2.5."

Control of a wilt disease of potato by formaldehyde dust, C. F. TAYLOR and F. M. BLODGETT (*Amer. Potato Jour.*, 14 (1937), No. 5, pp. 154-157).—This contribution by Cornell University indicates that treatment with formaldehyde dust reduces the injury from this disease sufficiently to be of great importance in seed production, but that serious yield decreases may result if extreme precautions are not observed in using this method.

Disinfectants and cut-seed potatoes, B. F. LUTMAN (*Vermont Sta. Bul.* 418 (1937), pp. 36, pls. 4, figs. 13).—Cut potato seed, as well as desprouted whole tubers, may be seriously injured by certain disinfectants. The normal cork layer offers protection, but regenerated cork is much less effective.

Based on their action, seed-potato disinfectants are grouped into three classes—(1) formaldehyde and $HgCl_2$, so soluble in aqueous solutions as to be highly toxic to bacteria and fungi; (2) mercurous chloride (calomel) and yellow mercuric oxide, slightly water-soluble but sufficiently so to check the growth of soil parasites and forming a suspension from which the seed pieces remove much finely divided mercury salt; and (3) organic mercury compounds, readily soluble in water and applied for a brief time only, their efficiency due primarily to the salt adhering after the dip. Formaldehyde proved most injurious to cut seed, not only penetrating the exposed parenchyma but working its way along the vascular bundles and even into the sprouts. Solutions of $HgCl_2$ kill the seed pieces by coagulating the protoplasm and percolate farther into the flesh the longer the piece is kept. Immediate removal of the coagulated layer lessens the penetration, which otherwise may kill the sprouts on planted seed pieces. The proportion of calomel absorbed is so small that no injury ensues in the seed pieces, and hence the seed thus disinfected usually germinates well. Yellow oxide of mercury behaves much like calomel. The brevity of application and quick drying of organic mercurials result in a fair and prompt depth of penetration, and the residue comes into action gradually. If drying follows immediately and completely, the cut piece is undamaged. These results are based on 5 yr. of field and greenhouse tests under both dry and wet conditions and have been substantiated by penetration studies and by chemical determinations of the amounts of mercury removed from various solutions or suspensions.

If cut tubers are to be disinfected they should be allowed to regenerate a new skin by storage for at least 5 days in a damp, cool place. Calomel, yellow oxide of mercury, or one of the organic mercurial dips should be used, preferably the latter (with prompt and thorough drying).

Chemical studies on the virus of tobacco mosaic.—VII, An improved method for the preparation of crystalline tobacco mosaic virus protein, W. M. STANLEY (*Jour. Biol. Chem.*, 115 (1936), No. 3, pp. 673-678).—Continuing this series (E. S. R., 76, p. 206), "an improved method for the preparation of crystalline tobacco-mosaic virus protein, involving the use of ammonium sulfate, celite, and calcium oxide, and by means of which the yield from crude twice-precipitated globulin has been increased to about 80 percent, is described."

Tumors of tobacco hybrids, M. LEVINE (*Amer. Jour. Bot.*, 24 (1937), No. 5, pp. 250-256, figs. 17).—Comparisons are made between artificially induced crown galls on *Nicotiana glauca* and *N. langsdorffii* and spontaneous tumors on crosses between these two parents when the latter is the male parent. The bacterial tumors were typical crown galls, with histioid structures consisting of a mass of parenchyma in which distorted, aberrant, bizarre fibrovascular elements were formed. The spontaneous tumors of the hybrid, closely resembling crown gall macroscopically, arose from a calluslike mass of parenchymatous tissue with cells frequently filled with starch and other bodies, presumably tannin. The stem forms were often globular and deep green in color, and the tissue mass resolved itself into organoids consisting of aberrant rudimentary stems and leaves. The peripheral portion was embryonic in nature, consisting of small cells with comparatively large nuclei. The fibrovascular elements were feebly developed and not disorganized or disconnected when seen in longitudinal median section of these organoids. Similar structures are reported on the crown of the geranium.

These spontaneous tumors are not identical with crown gall, and it is suggested that another type of growth is here concerned, having a calloid structure with differentiation of imperfectly formed stems and leaves. These may be compared to the monstrosities of teratomata among animal tumors.

Disease resistance and new seedling selection in 1936 at the U. S. Sugar Plant Field Station, Houma, La., E. V. ABBOTT, R. D. RANDS, and E. M. SUMMERS (*Sugar Bul.*, 15 (1937), No. 14, pp. 3-7).—During 1936 the general and specific objectives have remained as previously reported (E. S. R., 75, p. 645), with particular attention focused on the urgent necessity of discovering a vigorous, mosaic-resistant substitute for Co. 281 and the desirability of finding more suitable disease-resistant, early-maturing varieties adapted to heavy and mixed soils. A brief summary of progress in 1936 is presented, including the study of a large number of seedlings in the field (4,119 inoculated with mosaic, 998 with the red rot fungus, and 2,318 analyzed for Brix and sucrose), on the basis of which 117 new C. P. numbers were assigned to the cane breeder (G. B. Sartoris), and seed of these varieties were distributed for testing. The performances of promising selections and seedling family tests are presented.

A nematosis of sweet potatoes caused by *Anguillulina dipsaci*, the stem or bulb nema, H. A. KREIS (*Phytopathology*, 27 (1937), No. 6, pp. 667-690, figs. 6).—During a 1930 survey of 70 localities in the sweetpotato regions of New Jersey, Maryland, Delaware, Virginia, North Carolina, and South Carolina, *A. dipsaci* was found once only on sweetpotatoes in the field but in 6 localities in storage. On this host the disease appears to be mainly a storage condition. Infested roots have a brown to brownish-black layer under the skin, while in more advanced stages the whole interior shows signs of decay.

A differential count of the nemec population of an infested root by layers yielded 501,631 specimens. Toward the center the nemas occurred mostly in nests. Males gradually disappeared toward the center, and a decrease in total numbers of nemas from the outside toward the center was rapid after the first layer.

Transmission tests were made from sweetpotato plant to plant, from sweetpotato to potato tubers, and from other hosts to sweetpotato. The only positive conclusions were that the green parts of sweetpotato plants are not normally attacked, that transfer from one sweetpotato root to another occurs by contact, that the one transfer test from potato tuber to sweetpotato root was of too short duration to allow definite commitments, and that some nemas entered cut sweetpotatoes from an inserted piece of narcissus bulb.

Of the 24 tests directed toward a satisfactory chemical control in the root, only Semesan Bel and lime combined with phenol showed promise. Eradication of weeds in the fields, crop rotation, use of uninfested seed potatoes, and general sanitary methods in handling and storing the roots are recommended as control aids.

Comparative measurements of *A. dipsaci* from sweetpotatoes and from other hosts indicated a great variability in the forms, even from the same host. Differentiation of this nema into species or subspecies on the basis of hosts is therefore not favored.

Diseases of vegetable crops, J. C. WALKER (*Ann Arbor, Mich.: Edwards Bros., 1936, pp. [2]+65*).—"The purpose of this text is to bring together in outline form the important facts concerning the major diseases of the vegetable crops." The arrangement is alphabetical by common names of crop plants, under each of which the culture and diseases are discussed, with literature references.

Plasmodiophora brassicae, the cause of cabbage hernia, M. S. WORONIN (*Phytopath. Classics No. 4 (1934), pp. 32, pls. 7*).—With this translation of the author's early paper¹ is a biographical sketch of him by C. Chupp.

A transmissible mosaic disease of cauliflower, C. M. TOMPKINS (*Jour. Agr. Res. [U. S.], 55 (1937), No. 1, pp. 33-46, figs. 5*).—Through study by the California Experiment Station, it was found that this mosaic, due to a hitherto undescribed virus, occurs chiefly in the cool, coastal valleys of California, frequently causing considerable crop losses. It is characterized by stunting of the plant; vein clearing, followed by vein banding, mottling, necrotic spotting, midrib curvature, and distortion of the leaves; and dwarfing of the terminal head. The insect vectors are shown to be *Brevicoryne brassicae*, *Rhopalosiphum pseudo-brassicae*, and *Myzus persicae*. The virus is also transmissible by juice inoculations, with carborundum as an abrasive. It withstands aging in vitro for 14-15 days at 22° C., its inactivation temperature is approximately 75°, and its tolerance to dilution is about 1:2,000. The host range includes 51 vegetable varieties, 3 ornamentals, and 5 weeds, all Cruciferae.

Cantaloupe wilt is spreading in State, O. A. REINKING (*Farm Res. [New York State Sta.], 3 (1937), No. 4, pp. 10, figs. 2*).—The *Fusarium* wilt is reported as spreading and becoming increasingly destructive in the cantaloupe regions of the State, with total losses on thoroughly infected soils. The disease was first reported in the State in 1930 by C. Chupp. The symptoms are described. The fungus was shown to be present throughout the entire infected plant, and inoculations with various isolates readily resulted in infection, the organism exhibiting extreme virulence under optimum conditions for

¹ Jahrb. Wiss. Bot., 11 (1878), pp. 548-574, pls. 6.

disease production and 100 percent of the susceptible varieties tested (and named) succumbing in inoculated soil. The disease is evidently identical with the one reported from Minnesota (E. S. R., 69, p. 669). *Fusarium* wilt was demonstrated to be seed borne and the fungus to remain infective in the soil for at least 2 yr.

The planting of seed from healthy plants, avoidance of infected soil, and the ultimate development of resistant varieties constitute the control measures recommended. "The demonstration of resistance within the edible varieties of cantaloups shows that it should be possible to obtain a commercial resistant type that will meet the needs of New York growers."

Phytophthora rot of Honeydew melon, C. M. TOMPKINS and C. M. TUCKER (*Jour. Agr. Res. [U. S.], 54 (1937), No. 12, pp. 933-944, figs. 4*).—This rot was found in part of a commercial planting near Modesto, Calif., where the soil had become waterlogged from poor drainage. It affects both immature (green) and mature (ripe) fruits, but not the vines, symptoms consisting of small, incipient brown or water-soaked spots which enlarge to form water-soaked lesions. Occasionally infected fruits develop zonate lesions. The invaded tissues are soft, water-soaked, and odorless.

In this joint contribution by the California and Missouri Experiment Stations, the causal organism was identified as *P. capsici*, infection with which was obtained by placing inoculum on the unbroken fruit surfaces and covering with moist absorbent cotton under an inverted preparation dish. The incubation period varied from 4 days for immature to 6 days for mature fruits. Excessive irrigation, poor drainage, and high temperatures were found to be the chief predisposing factors. Negative results were obtained in seed-transmission tests. In addition to Honey Dew melon, the fungus proved pathogenic to 14 species of 11 genera belonging to 6 families. Avoidance of the disease involves good soil drainage and careful irrigation practices.

Infection of Honey Dew melons by *P. drechsleri* was also demonstrated, but this fungus spread less rapidly through the tissues, which remained firm.

Cytological studies on the parasitic relationship of *Urocystis cepulae* to *Allium fistulosum*, R. I. EVANS (*Amer. Jour. Bot., 24 (1937), No. 4, pp. 214-218, figs. 17*).—As a result of this study by the University of Wisconsin it was found that *A. fistulosum* seedlings ultimately producing smut-free plants are consistently and successfully parasitized by the onion smut fungus in the upper parts of the cotyledons, while at least the lower halves are consistently free from infection. Little difference in incidence and severity was observed at soil temperatures of 10°-26° C. Healthy mycelium may develop in the upper part of the cotyledon, the result being abundant chlamydospore formation. When penetration of the lower part of the cotyledon is accomplished there is (1) almost immediate complete inhibition of the fungus, (2) partial inhibition followed shortly by disorganization, or (3) establishment of the fungus in the deeper host tissues before its ultimate disorganization. The defense mechanism of the cells in the lower part of the cotyledon appears comparable to that of onion seedlings in the transition stages leading from susceptibility to resistance.

A. fistulosum seedlings possess a considerable resistance to damping-off as compared with onion seedlings of like age.

Common mosaic of the garden pea, *Pisum sativum*, D. M. MURPHY and W. H. PIERCE (*Phytopathology, 27 (1937), No. 6, pp. 710-721, figs. 2*).—The symptoms induced by pea virus 3 on garden peas are characterized by variations ranging from severe yellow mottling and dwarfing to less intense mottling and a general chlorosis. The host-range tests in this study by the Idaho Experiment

Station included 2,424 annual and perennial plants representing 32 families, 60 genera, and 94 species. Infection was noted in only 1 family (Leguminosae). Species of *Medicago*, *Medilotus*, and *Trifolium* were found infected, and certain plants of these species may be possible overwintering hosts. The 63 garden-pea varieties tested were found to vary in resistance and susceptibility, as were also the field-pea varieties tested. Of a total of 4,263 seedling garden-pea plants grown under controlled conditions from seed collected from diseased plants, none gave evidence of seed transmission. The virus was inactivated by heating at 60° C. for 10 min. and by aging in vitro for 3 days at 22°.

It is concluded that the data presented on symptom expression by differential hosts, host range, modes of transmission, and physical properties of the common pea-mosaic virus (pea virus 3) are sufficient to differentiate it from other légume viruses.

The Riverside tomato: A new variety resistant to two wilt diseases, J. W. LESLEY and M. SHAPOVALOV (*Seed World*, 41 (1937), No. 7, pp. 8, 9, figs. 3).—The Riverside tomato variety, developed cooperatively by the California Citrus Experiment Station and the U. S. Department of Agriculture, is described and illustrated. It is reported to be suitable for both fresh consumption and canning and to be resistant to both *Fusarium* and *Verticillium* wilt diseases.

Rosette or little leaf of fruit trees, H. E. THOMAS (*Phytopathology*, 27 (1937), No. 6, pp. 727-729).—This contribution by the University of California is a critique of the published work of Kozłowski (E. S. R., 77, p. 61) on the etiology of this disease. It is stated that "one of the most consistent facts that has emerged from this complex problem is that of complete recovery of affected trees treated by the introduction of zinc, in any one of several forms, into the trunks or main branches."

Zinc sulphate treatments for "little leaf" condition of deciduous fruits, O. T. McWHORTER (*Oreg. State Hort. Soc. Ann. Rpt.*, 28 (1936), pp. 121-124).—This contribution from the Oregon State College presents a summary of successful trials of zinc-containing sprays, dusts, and injections, and metallic zinc in controlling little leaf on sweet cherry, apricot, prune, and apple.

Apple scab spray service for 1936, R. C. BAINES (*Ind. Hort. Soc. Trans.*, 1935, pp. 71, 72).—This is a contribution by the Indiana Experiment Station.

Spray materials and the control of apple scab and cedar rust, J. M. HAMILTON (*Amer. Pomol. Soc. Proc.*, 51 (1935), pp. 194-199).—This contribution by the New York State Experiment Station comprises a general discussion based on experiments in the Hudson Valley.

The "transitional apple spray period", F. W. HOFMANN (*Va. Fruit*, 25 (1937), No. 5, pp. 20-22).—From tests by the Virginia Experiment Station it was found that excellent results in disease control with reduction in spray injuries may be obtained by various wettable sulfurs, flotation sulfur, monocalcium sulfide, etc., and also by their admixture with lime-sulfur or bordeaux sprays, if the apple trees have been thoroughly treated before the transitional period (the 2.5-3 weeks following petal fall) or when scab has already been materially reduced, or, perhaps, in lighter scab seasons. Under other conditions these less effective materials cannot be relied upon.

Spray injuries on the apple fruit, A. B. GROVES (*Va. Fruit*, 24 (1936), No. 9, pp. 16-22, figs. 2).—This contribution by the Virginia Experiment Station gives a general account of spray injuries, including the common types (illustrated) and factors influencing them.

The control of drought spot and corky core of the apple in British Columbia, H. R. McLARTY, J. C. WILCOX, and C. G. WOODBRIDGE (*Better Fruit*,

31 (1937), No. 10, pp. 12, 13).—Following brief discussions of these troubles and the history of the investigation, it is stated that applications of boric acid and borax to the soil gave perfect control without apparent injury to the trees. Spraying also gave good results, but caused some leaf injury. Analyses of the soil showed but little difference in boron content between orchards with and without the trouble, but the less the boron content of McIntosh fruit, leaves, or twigs the worse was the disease. Soil application of boric acid or borax around the trees at the rate of 30 lb. per acre is recommended for British Columbia.

Boron treatment was also beneficial in the control of drought spot of pear and apricot and of gum spot of plum trees.

Two species of *Physalospora* in England, N. E. STEVENS (*Mycologia*, 28 (1936), No. 4, pp. 330–336).—The relationship of two very similar fungi found on rotten apples in England and in New York, in each case named *Sphaeropsis mialorum*, has caused much controversy. This paper reports the finding in England of the ascogenous stages of both these fungi and the development of the pycnospores in pure culture from ascospores. The New York fungus is referred to *P. obtusa* and the fungus originally described from England to *P. mutila* n. comb.

Another pycnidial fungus, *Diplodia sarmentorum*, on the same hosts is discussed and its geographical distribution outlined.

Sclerotium disease on apple trees, J. S. COOLEY (*Amer. Nurseryman*, 64 (1936), No. 5, p. 7, fig. 1).—*S. rolfsii*, a fungus attacking herbaceous plants in the Southern States, is here reported as infecting apple trees in the nursery (Maryland and Tennessee).

The occurrence of aerial bacterial strands on blossoms, fruits, and shoots blighted by *Erwinia amylovora*, S. S. IVANOFF and G. W. KETT (*Phytopathology*, 27 (1937), No. 6, pp. 702–709, figs. 2).—In this study by the Wisconsin Experiment Station, bacterial exudate was found in the form of hair-like strands on pear pedicels, shoots, and fruits blighted by *E. amylovora* [= *Bacillus amylovorus*]. These strands were made up of cells of the pathogen bound together by a cementing substance. They were curved, glistening, usually colorless, from less than a millimeter to several centimeters long, and 8 μ –45 μ thick. The strands disintegrated instantly in water and slowly in glycerin. They were infective, and could be easily broken off and disseminated by the wind.

Frosty mildew of peach, B. B. HIGGINS and F. A. WOLF (*Phytopathology*, 27 (1937), No. 6, pp. 690–696, fig. 1).—The morphology and life cycle of *Cercospora persica*, causing frosty mildew of peach, was studied cooperatively by the Georgia Experiment Station and Duke University. It was found that, besides conidia, the fungus produces spermatogonia and perithecia. The conidial stage was made the type of the genus *Cercospora*, and it appears desirable thus to retain it and to enlarge Saccardo's concept of its generic limits. Both spermatogonia and perithecia are initiated simultaneously during the fall. Spermatial production ceases after about 2 mo., while the perithecia do not mature until the following spring. The perithecial stage apparently has never been observed before, and it is accordingly given the name *Mycosphaerella persica* n. sp.

Disease-free citrus trees is aim of experiment station, H. S. FAWCETT (*Calif. Citrogr.*, 21 (1936), No. 10, pp. 396, 397).—This paper is from an address summarizing progress by the California Citrus Experiment Station in control work on citrus diseases.

Chlorosis of citrus in Puerto Rico, J. H. JENSEN (*Phytopathology*, 27 (1937), No. 6, p. 731).—This contribution by the Puerto Rico Experiment Station reports the beneficial effects of zinc sulfate sprays in the control of a leaf chlorosis on grapefruit. Diseased trees were found only on alkaline soils. The symptoms are briefly described.

Some new aspects of gummosis and psorosis of citrus trees in Florida, A. S. RHODES (*Citrus Indus.*, 17 (1936), No. 10, pp. 6, 7, 15, 19, [23], figs. 4).—This contribution from the Florida Experiment Station is an address summarizing the results of several years of study and observation. The results with the bark disease emphasize the need for treating pruning and other wounds with an effective and durable dressing in order to obviate many cases of gummosis and prevent the entrance of the organisms of wood decay.

Effect of mottle leaf on fruit size, J. C. JOHNSTON (*Calif. Citrogr.*, 22 (1936), No. 2, pp. 86, 87, figs. 3).—Zinc treatments (as soil, injection, and spray applications) increased the average size and decreased the range of sizes of the fruit, the effect being to reduce the amount of undesirable small and large fruit. Best results followed the spray treatments.

Endoxerosis, or internal decline, of lemon fruits, E. T. BARTHOLOMEW (*California Sta. Bul.* 605 (1937), pp. 42, pl. 1, figs. 5).—The author discusses the characteristics of endoxerosis, the varieties affected, its general distribution, comparisons with *Alternaria* rot and membranous stain, and other pertinent data. Desiccation cavities adjacent to the vascular bundles in the peel of the stylar end of the fruit were the first symptoms noted, and the development of subsequent symptoms is described in detail. About 10–15 percent of the fruit picked from May 1 to November 1 in southern California was found to be affected. Fruits growing slowly or very rapidly were more susceptible than those growing at intermediate rates. The amount of acid was reduced in proportion to the injury, but its strength was about as great as in normal fruits. Partial defoliation or enclosure of the trees in tents was followed by a decrease of the trouble. Comparatively large amounts of water were withdrawn from the fruits by the transpiring leaves, and the daily contraction of the fruit from this cause began earlier and lasted longer in the long, dry summer days than in winter and in endoxerotic as compared with normal fruits. Twigs that had borne affected fruits withdrew much less water from potometers than those which had borne normal fruits, and the amounts of gas which could be forced through the twigs were less in the first case. The gum characteristic of affected fruit appeared to be formed largely from the cell-wall components and that of the twigs largely from the cell contents. The gum-forming pentosans were much more abundant in the peel of affected fruits, and the first indication of gumming appeared in the vascular region of the peel of the stylar end, progressing from that point. Examination of 1,782 twigs showed no relation between the presence of gum in the pith and the development of endoxerosis.

In tank experiments, trees receiving the minimum amount of water developed more endoxerosis than those with the medium, and the latter slightly less than those with the maximum amounts. Also, the total amount of fruit with medium water supply was considerably greater than with minimum and slightly greater than that with maximum supply. Varietal differences in susceptibility were inconsistent. The time of first appearance depended largely on the rainfall of the previous winter, and more endoxerosis developed on the south than on the north side of the trees. The factors governing the number of developed v. undeveloped seed, variations in fertilizers, and bagging the fruit appeared to have no relation to the development of the trouble.

In general, the data indicate that daily and protracted water deficits in the tissues concerned, high temperatures during the active growing season, and the presence of substances more or less readily convertible into gum are the most important etiological factors. The strong inclination to gum production in citrus under adverse conditions was confirmed.

Various control or alleviative measures for grove and packing-house use are suggested, notably the use of a smaller picking ring during the warm months.

Notes on rust diseases of *Sempervivum* and other ornamentals in the New York area, B. O. DODGE and G. M. REED (*Jour. N. Y. Bot. Gard.*, 37 (1936), No. 435, pp. 54-59, figs. 4).—This paper consists of notes on rust of *S. tectorum* due to *Endophyllum sempervivi*, on rust of rhododendrons and azaleas due to *Pucciniastrum myrtilli*, and on rusts of carnation, snapdragon, chrysanthemum, and hollyhock.

Effect of heat on ability of *Cicadula sexnotata* (Fall.) to transmit aster yellows, L. O. KUNKEL (*Amer. Jour. Bot.*, 24 (1937), No. 5, pp. 316-327, figs. 3).—"Infective colonies of aster leafhoppers subjected to heat treatments lasting 1 day or longer at about 31° or 32° C. [87.8° or 89.6° F.] lost the ability to transmit yellows either permanently or temporarily. The colonies held at these temperatures for 12 days or longer suffered permanent loss of ability to transmit. Colonies treated from 1 to 11 days regained ability to transmit after periods varying from a few hours up to many days. The longer the colonies were heat-treated, the longer it took them to regain ability to transmit. . . . These findings are believed to indicate that long heat treatments cause inactivation of all the virus carried by infective insects, and that short heat treatments cause inactivation of a part only. The time required for insects to regain infectivity is regarded as a heat-induced incubation period during which that portion of the virus not inactivated by the treatment multiplies sufficiently to render the insects infective. The fact that heat treatments have a more marked effect on colonies in which virus is undergoing natural incubation than on infective colonies is interpreted as due to a lower concentration of virus in the latter than in the former.

"After heat treatments, viruliferous colonies of insects frequently transmitted mild strains of the aster-yellows virus. Three such strains were shown to remain unchanged on passage from plant to plant. Isolation of mild strains by this method suggests that heat exerts some kind of selective action on the viruses of mild strains.

"The rate of spread of aster yellows in a field plat was found to reach its highest point late in the season when plants were relatively resistant to infection because they were nearing maturity and when insects were less numerous than in midsummer. The heat treatment experiments suggest that mid-summer temperatures may inactivate much of the virus carried by the leafhoppers at this season of the year, and that the temperature effect on virus-bearing insects may account for the late seasonal rise in rate of spread."

The perfect stage of *Botrytis convoluta*, F. L. DRAYTON (*Mycologia*, 29 (1937), No. 3, pp. 305-318, figs. 9).—Under carefully controlled conditions, combined with the use of microconidia for spermatization, the convoluted sclerotial masses of *B. convoluta* (cause of a rhizome rot of iris) developed apothecia of the *Sclerotinia* type, thus establishing the connection of this ascigerous stage *S. convoluta* n. sp. with the conidiophores and conidia of the imperfect stage *B. convoluta*.

Artificial defoliation of field-grown rose plants.—Preliminary report, G. T. BOYD and J. J. TAUBENHAUS (*Amer. Rose Ann.*, 1936, pp. 130, 131; *ads. in Texas Sta. Circ.* 79 (1937), pp. 23, 24).—"Commercial defoliation of rose plants

during fall harvest is desirable to prevent numerous plant diseases from being carried over in storage on the old clinging leaves. Defoliation occurred with a spray consisting of 1 pt. commercial sulfuric acid, 2 lb. of iron sulfate, and 50 gal. of water. Only Paul's Scarlet Climber plants were used in the 1935 tests."

[The 1935 and 1936 disease-control campaigns], L. M. MASSEY (*Amer. Rose Ann.*, 1936, pp. 110-116; 1937, pp. 101-107).—These contributions from Cornell University discuss the progress made in the rose disease-control campaign initiated in 1934, with a tabulation of the returns, including observations in 34 States.

A bothersome black-spot experience, H. R. ROSEN (*Amer. Rose Ann.*, 1937, pp. 121-126).—This contribution by the Arkansas Experiment Station reports the disease as of epidemic proportions in 1935. The results of small-scale spray tests were rather unsatisfactory, but several rose varieties stood up well against the disease even without fungicidal treatment.

Sunscauld of tulip flowers, A. H. GRAVES (*Phytopathology*, 27 (1937), No. 6, pp. 731-734, fig. 1).—The injury is ascribed to sunscauld, due to the facts that in some varieties the flowers were injured when exposed to the sun but remained normal in the shade and that the tissues immediately adjacent to the principal veins remained uninjured. Lists of susceptible and resistant varieties are given.

The life histories of *Botryosphaeria melanops* and *Massaria platani*, C. L. SHEAR and R. W. DAVIDSON (*Mycologia*, 28 (1936), No. 5, pp. 476-482, figs. 5).—*B. melanops* was collected from red oak (*Quercus borealis*) in Connecticut and *M. platani* from a canker on a sycamore tree in Washington, D. C.

Chestnut breeding work in 1935, A. H. GRAVES (*Brooklyn Bot. Gard. Rec.*, 25 (1936), No. 2, pp. 62-75, fig. 1).—This report covers hybridizing work and testing of various species and strains with a view to securing desirable types resistant to the chestnut blight (*Endothia parasitica*).

A new species of *Dothiorella* causing die-back of elm, A. F. VERRILL and C. MAY (*Mycologia*, 29 (1937), No. 3, pp. 321-324, figs. 6).—*D. ulmi* n. sp. is described as the pycnidial form of the fungus previously reported as causing the disease commonly known as the *Cephalosporium* die-back of elm.

A report on tests of fungicides for the control of elm diseases in nurseries, J. C. CARTER (*Ill. Nat. Hist. Survey, Biol. Notes No. 4* (1935), pp. [2]-7, fig. 1).—The materials and methods are discussed, and the results are tabulated, with accompanying notes.

Current studies on the bacterial blight diseases of filberts and its control, P. W. MILLER (*Oreg. State Hort. Soc. Ann. Rpt.*, 28 (1936), pp. 152-159).—Filbert blight (due to *Phytonomas* sp.) is reported as very prevalent in the Pacific Northwest in 1936, its severity probably being associated with rainy weather during the critical infection period and with the unseasonably low temperatures of early November 1935, which seemed to predispose to attack. The disease was found for the first time on the fruit, but crop losses were largely indirect due to the killing of many of the pistillate flower buds, nut-bearing shoots and branches, and leaves. Two critical infection periods occur, viz, (1) in the fall and early winter and (2) in the early spring, the first being more favorable to infection. In 1936 the peak of the disease was reached in late May. Spraying with 4-4-50 bordeaux mixture during late August or early September 1935, before the first fall rains, appreciably reduced the disease incidence traceable to drip from infection sources in the trees. Spring applications appeared to result in a limited reduction in incidence.

New hosts and distribution of *Rehmiellopsis bohémica*, A. M. WATERMAN (*Phytopathology*, 27 (1937), No. 6, pp. 734-736).—The needle and twig blight

fungus of fir was reported previously on *Abies concolor* in Massachusetts, Maine, and New York. It has now been found in Rhode Island on *A. concolor* and *A. cephalonica*; in Edgewood, British Columbia, on *A. lasiocarpa*; and in Maine on *A. balsamea*. The last two species have not been reported previously as hosts. Infection occurred on small nursery trees of *A. nobilis* and *A. fraseri* planted among the most severely diseased trees in eastern Massachusetts. The former species has been reported as a host for the fungus in Denmark and Scotland only, and the latter has not been reported previously.

Two spruce-infecting rusts, *Chrysomyxa piperiana* and *Chrysomyxa chionensis*, J. H. FAULL (*Jour. Arnold Arboretum*, 17 (1936), No. 2, pp. 109-114).—The two species and inoculations with them on *Picea* species are described.

Opuscula miscellanea nematologica, III-V, G. STEINER (*Helminthol. Soc. Wash. Proc.*, 3 (1936), Nos. 1, pp. 16-22, figs. 4; 2, pp. 74-80, figs. 4; 4 (1937), No. 1, pp. 33-38, figs. 5).—Continuing this series (*E. S. R.*, 74, p. 509), the author describes in part 3 *Rhabditis spiculigera* n. sp., associated with a strawberry root rot from Ontario; *Neocephalobus leucocephalus* n. sp., feeding on *Ceratostomella* sp., a fungus living in the scarlet oak (*Quercus coccinea*), from Virginia; and *Rhabditolaimus* (*Rhabdiontolaimus*) *prodelphis* n. sp., and *Eucephalobus nannus* n. gen. and n. sp., both from diseased *Iris ochroleuca* plants from Long Island. Part 4 includes observations of nematodes in bulbs of an *Iris tingitana* hybrid, with a description of *Aphelenchoides limberi* n. sp.; a description of the *Acrobeles variabilis* n. sp. observed in diseased *Ixia* bulbs; a description of *A. bodenheimeri* n. sp., a new nematode from Palestine; observations on *Tricephalobus longicaudatus*; and remarks concerning *A. crossotus*. Part 5 describes *Tylenchorhynchus claytoni* n. sp., an apparently rare nematode parasite of tobacco; *Rotylenchus blaberus* n. sp., a nematode parasite of yams (*Dioscorea* sp.); and *Anguina spermophaga* n. sp., a seed parasite of *Saccharum spontaneum*; and presents notes on *Heterodera marioni* attacking bulbs of *Ornithogalum saundersiae*.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Ecological animal geography, prepared by W. C. ALLEE and K. P. SCHMIDT (*New York: John Wiley & Sons; London: Chapman & Hall*, 1937, pp. XIV+597, figs. [137]).—Part 1 of this authorized, rewritten edition based on Tiergeographie auf oekologischer Grundlage, by R. Hesse, published in 1924, considers the ecological foundations of zoogeography (pp. 1-145); part 2 the distribution of marine animals (pp. 146-287); part 3 the distribution of animals in inland waters—a phase of limnology (pp. 288-376); and part 4 the distribution of land animals (pp. 377-556). Bibliographies accompany the chapters, of which there are 28.

Regulations relating to game, land fur animals, and birds in Alaska, 1937-38 (*U. S. Dept. Agr., Bur. Biol. Survey, Alaska Game Comm. Circ. 14* (1937), pp. 32, fig. 1).—A compilation of these regulations applicable to the year 1937-38 (*E. S. R.*, 75, p. 654).

The snowshoe rabbit or varying hare (*Lepus americanus*, L. *campes- tris* (?)) (*Alaska Sta. Bul. 5* [1936], pp. 18, 19).—Reference is made to the cause of the periodical rise and fall in the rabbit population of Alaska, the average cycle of which in the Fairbanks area commencing with 1905 has been 10 yr.

Crow-waterfowl relationships, based on preliminary studies on Canadian breeding grounds, E. R. KALMBACH (*U. S. Dept. Agr. Circ. 433* (1937), pp. 36, pls. 3, figs. 15).—A study inaugurated in the spring of 1934 and con-

tinued through the nesting season of that year and of 1935, conducted with a view to obtaining a current insight into the relationship of crows to waterfowl on their breeding grounds, is reported. Due to the drought conditions the studies were restricted to Canadian areas in Saskatchewan and Alberta, where ducks and crows could be found in reasonable abundance and in close association. The field studies revealed that there are areas near the northern border of agriculture in these two Provinces in which the presence of an inordinately dense crow population is a menace to duck-nesting marshes, but that where crows are less abundant, as in the pot-hole country about Prince Albert, Saskatchewan, losses are correspondingly less severe.

The methods of approach and the problem of the crow on waterfowl breeding grounds are first discussed. Nest observations and analysis of results, the food of crows as revealed by stomach examination, and the value of remedial measures are reported upon.

The shore birds, cranes, and rails: Willets, plovers, stilts, phalaropes, sandpipers, and their relatives deserve protection, A. A. ALLEN (*Natl. Geogr. Mag.*, 72 (1937), No. 2, pp. 183-222, pls. 16, figs. 4).—This is the sixteenth of the series of articles describing the bird families of the United States and Canada, illustrated by paintings by A. Brooks (*E. S. R.*, 76, p. 821).

Birds of the island of Java, I, II, N. KURODA (*Tokyo: Author*, 1933, vol. 1, pp. XV+370, pls. [15]; 1936, vol. 2, pp. VI+371-794, pls. [21]).—A preface and an introduction to this work in volume 1 are followed by a historical sketch on the ornithology of Java (pp. 1-26). A description of the adults, distribution, field notes, and a brief synonymy are given for each form in the systematic part, which composes the remainder of the volume and treats the order Passeres. Volume 2, which treats the whole nonpasserine birds (pp. 371-695), includes a summary and conclusion, a table concerning the distribution of the avifauna of Java and the vicinity, lists of the avifauna occurring in the principal islands of the Lesser Soenda (Sunda) Islands, and a bibliography of 15 pages. Keys to the genera and species, indexes to the systematic and local names, and a sketch map of Java are included in both volumes. The work is illustrated by 34 colored plates, all but 1 of which, sketched by N. H. Kuroda, are by S. Kobayashi. The avifauna of Java at the time of preparation of the work consisted of 510 species and subspecies, representing 25 orders and 62 families.

A supplement to the Birds of Norfolk & Lord Howe Islands to which is added those birds of New Zealand not figured by Buller, G. M. MATHEWS (*London: H. F. & G. Witherby*, 1936, pp. XIV+177, pls. [57], [figs. 7]).—This supplement to the author's work on the Birds of Norfolk & Lord Howe Islands, said to be more properly a supplement to his Birds of Australia, both of which have been noted (*E. S. R.*, 62, p. 417), includes the birds of New Zealand. Most of the forms are illustrated by colored plates.

Reptiles and amphibians in relation to celery insects in the Sanford, Florida, district, D. STONER (*Fla. Ent.*, 19 (1937), No. 4, pp. 49-53, fig. 1).—Observations of the amphibian and reptilian fauna of celery fields at Sanford, made during the course of studies particularly of the greenhouse leaf tier (*E. S. R.*, 68, p. 356), are reported. Three successive autumn and winter seasons of 6 mo. each are said to have been devoted to field and laboratory work.

The life histories of three trematodes, parasitic in birds and mammals, belonging to the genus *Plagiorchis*, D. B. McMULLEN (*Jour. Parasitol.*, 23 (1937), No. 3, pp. 235-243, figs. 8).—In experimental infections the adults of three species of trematodes of the genus *Plagiorchis*, namely *P. muris*, *P. micracanthos*, and *P. proximus*, were obtained. "The first intermediate host for

the three species has been found to be *Stagnicola emarginata angulata*. Usually the second intermediate hosts were aquatic insects. The precocious development of the cercariae into metacercariae without leaving the sporocyst was observed in *P. muris* and *P. proximus*. The adults of *P. muris* were obtained in experimental infections of man, rat, mouse, and pigeon. Natural infections were found in the nighthawk, robin, herring gull, and spotted sandpiper. Adults of *P. micracanthos*, a lat parasite, have been obtained in experimental mice. Adults of *P. proximus*, a parasite in the muskrat, have been obtained in small numbers in experimental mice."

Another record of avian schistosomes in North America, R. T. YOUNG (*Jour. Parasitol.*, 23 (1937), No. 3, pp. 295, 296).—The finding of schistosomes in a marbled godwit (*Limosa fedoa*) in California is added to the six or seven records on the finding of avian schistosomes in North America.

An introduction to entomology, J. H. COMSTOCK (*Ithaca, N. Y.: Comstock Pub. Co.*, 1936, 8. ed., rev., pp. XIX+1044, pl. 1, figs. 1228).—A new edition of this work (E. S. R., 53, p. 252), revised by G. W. Herrick.

A manual of entomological equipment and methods, II, A. PETERSON (*St. Louis, Mo.: John S. Swift Co.*, 1937, pt. 2, pp. 334, pls. 21).—Part 2 of the work previously noted (E. S. R., 72, p. 215) attempts a complete compilation of abstracts and original contributions on rearing information found in English. In addition, abstracts are included on "marking insects, shipping or transporting living insects and pinned specimens, collecting insects, and photography related to insects. No attempt, however, has been made to assemble all the literature on these topics. Many miscellaneous notes on museum and laboratory methods are also included. Some of these present information on sampling, catching, trapping, killing, mounting, preserving, dissecting, inflating, labeling, drawing, clearing, staining, insect diseases, pollination, plant disease transfer, etc." Part A of the index (pp. 315-326) takes up rearing information, the arrangement being by scientific and common names; part B (pp. 327-334), equipment and methods.

Effect of different soaps on formation of soluble arsenic from lead arsenate in soft and hard waters, J. M. GINSBURG (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 583-590).—In experiments by the New Jersey Experiment Stations, conducted with lead arsenate mixed with soluble and insoluble soaps in soft and in hard water for the purpose of determining the extent to which soaps may safely be used as spreaders and correctives with arsenical sprays, it was found that "(1) water-soluble soaps increase the soluble arsenic in soft water in proportion to the amount of soap added; (2) hard waters form large amounts of soluble arsenic, especially when the hardness is due to carbonates or bicarbonates; (3) soluble soaps, added to hard water, prevent the formation of excessive amounts of soluble arsenic; (4) soluble soaps react with the salts present in hard water, precipitating the corresponding insoluble soaps which apparently do not affect the lead arsenate; (5) certain insoluble metallic soaps when added directly to the lead arsenate also prevent formation of water-soluble arsenic in hard water; (6) of the various salts causing water hardness the bicarbonates and carbonates are primarily responsible for the production of soluble arsenic from lead arsenate; [and] (7) while in hard water the presence of soluble soap may make lead arsenate safer on foliage, the addition of soaps to soft water may result in increased arsenical injury."

Supplements in dormant bordeaux sprays for insect control on citrus, W. L. THOMPSON (*Citrus Indus.*, 18 (1937), No. 1, pp. 8, 9, 21).—Control work with citrus insects and mites conducted during 1936 in the Vero Beach sec-

tion by the Florida Citrus Substation is referred to, with particular attention to 4 of 12 different materials used in combination with bordeaux mixture. The details are presented in two tables.

Wettable sulfur as a supplement for lime-sulfur, copper, and zinc sprays, W. L. THOMPSON (*Citrus Indus.*, 18 (1937), No. 3, pp. 5-7, 18, 19, figs. 4).—Wettable sulfur was found by the Florida Citrus Substation to be a safe and effective supplement for lime-sulfur, bordeaux mixture, and other copper sprays and for the recommended zinc sprays. Application at the rate of from 5 to 6 lb. per 100 gal. appears to be the most economical amount to add to lime-sulfur for citrus rust mite control. "A larger amount may result in a little longer period of protection, but the added cost of the material may offset that advantage unless the period is long enough to reduce the number of applications necessary during a season. If [purple] scale control is to be considered, the amount of wettable sulfur may be increased to advantage, especially if a weak solution of lime-sulfur is used. The same recommendations hold true in copper and zinc sprays; that is, if wettable sulfur is added for rust mite control 5 lb. per 100 gal. is sufficient, but if scale crawlers are present the amount should be increased to 10 lb."

Tests with summer-oil emulsions on peach, S. W. FROST (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 658-663, fig. 1).—In experiments at the Pennsylvania Experiment Station "slight injury resulted from the applications of sulfur-oil combinations to peach during 1936. This was due partly to the extremely weakened condition of the trees, also to early dates of application. Although the percentage of injury indicated in the tables seems high, the actual injury to the trees was almost negligible. By selecting a suitable type of sulfur, the injury can be reduced. One percent actual soap by volume seems sufficient to kill the summer broods of peach lecanium [the terrapin scale]. One-half percent is not sufficient."

Effects of the alkaloid nicotine on the rhythmicity of isolated heart preparations from *Periplaneta americana* and *Prodenia eridania*, J. F. YRABEE and J. B. GAHAN (*Jour. Agr. Res. [U. S.]*, 55 (1937), No. 1, pp. 1-19, figs. 5).—Experiments performed to detect the effects of different concentrations of nicotine upon the contraction rates of isolated insect heart preparations immersed in a perfusion fluid of known composition and temperature when the pH values of the fluid, with and without dissolved nicotine, fall within the approximate range of 6.8 to 7.8 are reported. The contribution is presented with a list of 44 references to the literature cited.

Effects of nicotine fumigation at short exposure and assumed high concentration, J. F. ALSTERLUND and C. C. COMPTON (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 571-575, figs. 3).—This contribution from the Illinois Experiment Station, in cooperation with the Illinois Natural History Survey, presents evidence from a series of experimental greenhouse fumigations, together with data from outdoor field fumigation, of the pea aphid, which indicates that nicotine vapor is most efficient as an aphicide if an assumed high concentration of fumes is built up for a relatively short period, rather than maintaining a weaker dosage over a longer exposure. The qualification "assumed high concentration" is made since no reliable method of quantitatively sampling air for the presence of nicotine vapor was available. "The toxic action of the nicotine vaporizer in field fumigation of the pea aphid appears to be essentially similar to the spot fumigation of greenhouse aphids [*chrysanthemum* aphid]. In both cases there was a very short exposure to a comparatively dense concentration of nicotine vapor, with resulting high and consistent kill. In the greenhouse tests the spot fumigation method was clearly superior to the traditional practice of allow-

ing the nicotine vapor to diffuse equally throughout the house from stationary points."

Laboratory apparatus for fumigation with low concentrations of nicotine, with studies on aphids, H. H. RICHARDSON and R. L. BUSHEY (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 576-582, figs. 3).—A description is given of a laboratory apparatus in which "air flows varying in nicotine concentration from 42 to 0.25 p. p. m. (0.278 to 0.0016 mg per liter) have been obtained, thereby making possible toxicity studies with aphids. Still lower concentrations may evidently be obtained if desired. Glass containers with ground-glass connections are used in that part of the apparatus through which nicotine gas flows. Compressed air regulated by needle valves and measured by calibrated flow meters is used for air flows. Nicotine concentrations were determined by microchemical analysis of the gas. One-half-hr. exposures at $77^{\circ} \pm 0.9^{\circ}$ F. were used in all tests.

"Nicotine fumigation was at first much more effective at low relative humidity than at high. Possibly the absorption of the nicotine by the presumably heavier film of moisture present, though invisible, on the inside of the fumigation chamber under high humidity conditions would account for the lower mortality, for after sufficient nicotine has passed through the chamber the fumigation is just as effective at high as at low relative humidity. Concentrations of one part nicotine per million parts air (0.0066 mg per liter) killed large numbers of the peach aphid (*Myzus persicae*) from nasturtium, which were used in most of the tests. The bean aphid (*Aphis rumicis*) from nasturtium was somewhat less resistant than *M. persicae*, whereas the pea aphid (*Illinoia pisi*) from pea was more resistant."

Semicommercial manufacture of nicotine peat, L. N. MARKWOOD (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 648-651).—An account is given of the semicommercial manufacture of nicotine peat from New Jersey reed peat and German moss peat. "New Jersey peat is screened for the removal of impurities, dried to a moisture content of 10 percent, soaked in 2 percent hydrochloric acid, washed free of soluble matter, and then treated with nicotine in the presence of water. The mixture is dried and ground to a fine powder. German moss peat is treated directly with nicotine. Analyses of the two products are given. The nicotine content is about 10 percent, and the nicotine insolubility is 88 percent of the total for the New Jersey product and 68 percent for the German product. Standard commercial equipment, including a vacuum dryer and a centrifuge, was used."

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 676-682).—The notes here presented (E. S. R., 77, p. 507) include the following: Possible Migration of Diamondback Moth, by G. M. List (p. 676) (Colo. Experiment Station); Aseptic Rearing of Bark Beetles [*Dendroctonus* sp. and *Ips* spp.], by E. C. Holst (pp. 676, 677); *Diabrotica connexa* Lec. Transported in Vegetables, by L. J. Botilmer (p. 677); New Pest [*Tarsonemus bancrofti* Michael] of Sugar Cane in Continental United States, by J. W. Ingram (pp. 677, 678); Lime Sulfur to Control Forest Tent Caterpillar, by S. C. Jones (p. 678); Myiasis of Baby in Utah [Probably Due to *Wohlfahrtia meigeni* Shiner], by C. L. Rich and G. F. Knowlton (p. 678) (Utah Station); Recovery of Larvae [of the Raisin Moth and the Indian-Meal Moth] Paralyzed by *Microbracon hebetor* Say, by H. C. Donohoe (pp. 678, 679); Chemical and Insecticidal Tests of Samples of *Tephrosia toxicaria*, by H. A. Jones and W. N. Sullivan (pp. 679, 680); Indian-Meal Moth in California, by H. C. Donohoe (pp. 680, 681); Parasitism of Codling Moth Larvae by Native Parasites at Cornelia, Ga., in 1936, by J. E. Webb, Jr. (p. 681); and Relative Effectiveness

of Homologs of Paris Green Against Confused Flour Beetle, by W. W. Fassig and F. L. Campbell (pp. 681, 682).

Connecticut State entomologist, thirty-sixth report, 1936, W. E. BRITTON (*Connecticut [New Haven] Sta. Bul. 396 (1937), pp. 298-415+XI-XVI, figs. 34*).—Following a brief account of entomological features, with insect records for 1936 (pp. 293-310) (E. S. R., 75, p. 657), the inspection of nurseries, 1936, by Britton and M. P. Zappe (pp. 314-323) and of apiaries by Britton (pp. 324-330) and control work with the gypsy moth by Britton, J. T. Ashworth, and O. B. Cooke (pp. 330-339), the European corn borer by Zappe, N. Turner, and J. C. Schread (pp. 340-345), together with a brief account of its heavy infestation of potatoes in Suffield by Turner and Zappe (pp. 345, 346), and with the Japanese beetle in Connecticut by J. P. Johnson (pp. 346-351) are reported upon. Notes on the hymenopterous parasites of elm insects in Connecticut, by B. J. Kaston (pp. 351-361); contributions on the satin moth, by Britton (pp. 361-364); tests of apple sprays, by Zappe and E. M. Stoddard (pp. 364-366); further notes on *Calomycterus setarius* Roelofs, by Zappe (pp. 367-370) (E. S. R., 75, p. 232); control of potato leafhoppers on dahlias, by Turner (pp. 370, 371); observations on the European red mite and its control (pp. 372-377), work with oriental fruit moth parasites (p. 378), further studies in control of the apple maggot (pp. 378, 379), notes on control of the tent caterpillar in orchards (pp. 379-381), a note on field and laboratory control of cankerworms (pp. 381, 382), a report on peach sprays (pp. 382, 383), experiments with control of the rosy apple aphid (pp. 383-385), and a study of several nicotine preparations and wetting agents for increasing their toxicity (pp. 385-387), all by P. Garman; the horned squash bug *Anasa armigera*, with a note on *A. repetita* (pp. 387-391) and control of the striped cucumber beetle (pp. 391, 392), both by R. L. Beard; observations on termites and termite control, by Turner, Zappe, and J. F. Townsend (pp. 392-396); and the present status of mosquito control work in Connecticut, by R. C. Botsford (pp. 396-399), follow.

Miscellaneous insect notes presented (pp. 399-411) include the following: Outbreak of Say's blister beetle, the greenhouse leaf tier, the hickory leaf roller, elms injured by the rose chafer, scarcity of the fall webworm, the pepper maggot *Zonosemata (Spilographa) electa* Say in Connecticut, damage by the poplar sawfly *Trichiocampus viminalis* Fall, peach foliage eaten by a flea beetle (*Chalcoides (Grepidodera) helwincus* Linn.), peach trees injured by the New York weevil, the elm leaf beetle, prevalence of the forest tent caterpillar, a new mite on box (*Neotetranychus buxi* Garman), alders stripped by a sawfly (*Hemichroa americana* Prov.), damage by a new blister beetle (*Macrobasis forsa* Lec.), strawberries injured by *Diplofazis atlantis* Fall, house timbers injured by anobiid beetles (*Anobium punctatum* DeGeer (*striatum* Oliv.)), the lime tree looper, prevalence of the psychid moth *Fumea casta*, the fall cankerworm, bird mites in a dwelling house, damage by the spring cankerworm, decrease of the eastern tent caterpillar, and a new weevil (*Hylobius radialis* Buch.) injuring pine in Connecticut.

[Report of work in entomology by the Idaho Station], C. WAKELAND (*Idaho Sta. Bul. 221 (1937), pp. 30-33, fig. 1*).—The work of the year reported upon (E. S. R., 75, p. 658) relates to the production of very high kills of the beet leafhopper through the use of atomized petroleum oil, kerosene, and pyrethrum; increase in parasite control of the codling moth, San Jose scale, and woolly apple aphid; reduction of corn earworm injury through application of cryolite; control of the grape leafhopper by use of nicotine; increase in grasshopper and Mormon cricket populations; control of pea weevil by ap-

plication of derris and tobacco dust, cryolite, derris dust and diatomaceous earth, and derris dust and sulfur: and the influence of temperature and moisture on the movement of wireworms in soil.

[Report of work in economic entomology by the Kentucky Station] (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 24, 25, 33, 34, 44-47*).—The work of the year reported (E. S. R., 76, p. 65) includes the use of oil-nicotine spray (E. S. R., 77, p. 69), control of wireworm injury to tobacco plants, effect of burning tobacco beds to control white grubs, the tobacco flea beetle, control of May beetles, soil insecticides, white grub survey, dormant treatment for aphid control in orchards, trapping for green June beetles, controlling red spider on raspberry, relation of the pea aphid to clover and alfalfa failure, and the use of poisoned bran bait to control June beetle larvae in tobacco beds (E. S. R., 77, p. 508).

[Work in entomology by the Massachusetts Station] (*Massachusetts Sta. Bul. 339 (1937), pp. 46-61*).—Reporting upon the work of the year (E. S. R., 75, p. 512), reference is made to investigation of oil sprays for dormant applications, spray materials for the control of the gladiolus thrips, substitutes for lime-sulfur in summer sprays for orchards, derris and pyrethrum for the control of the greenhouse leaf tier on snapdragons, control of the cabbage maggot with mercury compounds, and control of the squash borer and apple maggot, all by A. I. Bourne and W. D. Whitcomb; control of the onion thrips, the spray residue problem and possible substitutes for lead arsenate, the introduction of parasites of the oriental fruit moth in peach orchards, potato spraying experiments, and insecticides for the control of the European corn borer, all by Bourne; insects concerned in the dispersal of Dutch elm disease, including the native elm bark beetle and other elm-boring insects, by W. B. Becker (E. S. R., 77, p. 359); the apple leaf-curling midge *Dasyneura mali* Kleff., naphthalene and similar compounds as greenhouse fumigants, the plum curculio in apples, control of the common red spider, and the biology and control of the carrot rust fly, all by Whitcomb; and the adaptability of *Cryptolaemus* to control of mealybugs in the greenhouse, by Whitcomb and W. Garland.

[Report of work in entomology by the Puerto Rico College Station], G. N. Wolcott (*Puerto Rico Col. Sta. Rpt. 1935, pp. 11, 12, 41-49*).—A brief report is made of the work during the year (E. S. R., 74, p. 228) on the life history of *Diaprepes abbreviatus* L. (E. S. R., 77, p. 225), the "hormiguilla" (*Myrmelachista ramulorum* Wheeler) and its control in coffee groves, introduction of predators into and from Barbados, status of the imported toad (*Bufo marinus* L.) (E. S. R., 77, p. 212), control of the West Indian peach scale *Diaspis pentagona* Targ. on papaya, the cottony-cushion scale, lima bean pod borer control, parasitism of the coffee leaf miner, the banana root borer, and insects as pollinating agents in coffee groves.

Insect control (*Rhode Island Sta. Rpt. [1936], p. 17*).—Brief reference is made (E. S. R., 75, p. 810) to control work with the cabbage maggot in which calomel dust was found inferior to corrosive sublimate and with aphids which severely damaged peas and tomatoes even though nicotine sulfate sprays were applied several times.

[Contributions on economic insects in England] (*Jour. Southeast. Agr. Col., Wye, Kent, No. 40, (1937), pp. 98-107, 115-147, 183-186, figs. 30*).—The contributions relating to economic insects and similar pests and their control (E. S. R., 77, p. 219) are: Investigations on the Insect and Allied Pests of Cultivated Mushrooms—IX, *Tyroglyphus dimidiatus* Herm. (*longior*) Gerv., by S. G. Jary and J. H. Stapley (pp. 119-129) X, *Sciara varians* Johns., Its

Occurrence Within a Mushroom House, With a Description of the Male Genitalia, by M. D. Austin and R. S. Pitcher (p. 98), and XI, The Long-Legged Mushroom Mite *Linopodes antennaeipes* Banks, by M. D. Austin (pp. 115-118), continuing the series noted below; Notes on Diplopoda—IV, The Recognition of Some Millipedes of Economic Importance, by S. W. Rolfe (pp. 99-107) (E. S. R., 72, p. 506): A Note on *Tyroglyphus longior* var. *castellani* (Hirst) (p. 130), The Identity of *Tyroglyphus siro* L. (Gerv.) (pp. 131-133), and Tests of Insecticides Against *Anthonomus rubi* (Herbst) (pp. 134-147), all by S. G. Jary; and "Meta-Fuel" and Slug Control, by S. G. Jary and M. D. Austin (pp. 183-186).

Entomological investigations, G. A. JULIUS ET AL. (*Austral. Council Sci. and Indus. Res. Ann. Rpt.*, 10 (1936), pp. 22-29).—The annual report on the progress of work with economic insects (E. S. R., 75, p. 808).

Biological control of noxious insects and weeds in New Zealand (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 7, pp. 579-593).—A symposium in which, following an introduction by D. Miller (pp. 579-581), the biological control of noxious weeds is considered by D. Miller (pp. 581-584), of forest insect pests by A. F. Clark (pp. 585-588), of fruit pests in New Zealand by L. J. Dumbleton (pp. 588-592), and of field crop and animal insect pests by D. Miller (pp. 592, 593).

Economic insects and biological control in the British Solomon Islands, R. J. A. W. LEVER (*Bul. Ent. Res.*, 28 (1937), No. 2, pp. 325-331, figs. 3).—This contribution reports upon biological control particularly of the hispid beetle *Brontispa froggatti* on young coconut palms and the buffalo fly *Lyperosia exigua* de Meij.

Investigations on the insect and allied pests of cultivated mushrooms, VI-VIII (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 38 (1936), pp. 67-74, figs. 4; 78-82, figs. 7; 83-85).—Three papers are presented in continuation of those previously noted (E. S. R., 76, p. 825): Observations Upon the Tyroglyphid Mite *Histioglyphus rostro-serratus* Megnin, by S. G. Jary and J. H. Stapley; Some Diagnostic Characters Used in the Determination of *Sciara* spp. (Family Mycetophilidae) Associated With Cultivated Mushrooms, by M. D. Austin and R. S. Pitcher; and Observations on the Larval Instars of *Sciara fenestralis* Zett., by R. S. Pitcher. Parts IX-XI are noted on p. 814.

[Work with cranberry insects by the Massachusetts Station], H. J. FRANKLIN (*Massachusetts Sta. Bul.* 339 (1937), pp. 36-39).—Economic insects of the year at the Cranberry Substation briefly reported upon (E. S. R., 75, p. 512) are the half-winged geometer *Phigalia titca* (Cram.), grape anomala (*Anomala errans* F.), fire beetle *Cryptocephalus incertus* Oliv., cranberry weevil, cranberry flea beetle *Systema frontalis* F., cranberry root grub *Amphicomma vulpina*, cranberry spittle insect (*Clastoptera*), gypsy moth, black-headed fireworm, and cranberry fruitworm and its parasite *Trichogramma minutum*. The use of kerosene-pyrethrum extract is discussed.

Insects of the British woodlands, R. N. CRYSTAL (*London and New York: Frederick Warne & Co.*, 1937, pp. XIII+338, pls. [12], [figs. 21]).—The forest insects of Great Britain are dealt with in eight chapters. Descriptions of some important forest insect genera and species and a list of the more important forest insects considered are given in two appendixes. A bibliography of four pages is included.

The insect menace in the bacteriology laboratory, D. PEASE (*Jour. Bact.*, 33 (1937), No. 6, pp. 619-624).—Attention is called to the danger of contamination in the laboratory of bacterial cultures by mites, particularly of the genera *Tyroglyphus* and *Tarsonemus*.

The control of mound colonies of *Eutermes exitiosus* Hill, F. G. HOLDAWAY and G. F. HILL (*Jour. Council Sci. and Indus. Res. [Austral.]*, 9 (1936), No. 2, pp. 195, 196, fig. 1).—A simple method for destroying mound colonies of *E. exitiosus* at slight expense through the use of arsenical powders is described.

The grasshopper situation in Iowa, C. J. DRAKE and G. C. DECKER (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 618-621).—A report from the Iowa Experiment Station on grasshoppers and the grasshopper situation in that State.

The grasshopper outbreak in Queensland, 1934-35, J. A. WEDDELL (*Queensland Agr. Jour.*, 47 (1937), Nos. 3, pp. 246-259, pl. 1, figs. 6; 4, pp. 354-364, figs. 14; 5, pp. 451-462, fig. 1).—Part 1 of this contribution deals with the history of grasshopper outbreaks in Queensland, part 2 with the life history and habits of *Chortioletes terminifera* Walk. in southeastern Queensland, and part 3 with control measures.

A study of spontaneous locomotor activity in *Locusta migratoria migratorioides* (R. & F.) by the actograph method, E. B. EDNEY (*Bul. Ent. Res.*, 28 (1937), No. 2, pp. 243-278, figs. 16).—A description is given of an actograph apparatus for recording in 24-hr. periods under controlled conditions the activity of *L. migratoria migratorioides* in terms of distance traveled. Great variation was observed in the amount of activity shown by different individuals, and the activity of any one individual is shown to vary considerably over each stadium, the highest level occurring about half-way between molts and falling off toward the beginning and end of each stadium.

Pristhesancus papuensis Stal., an "assassin" bug, N. S. NOBLE (*Jour. Austral. Inst. Agr. Sci.*, 2 (1936), No. 3, pp. 124-126, fig. 1).—Observations of the biology of this, the largest species of predaceous bug of the family Reduviidae occurring in Australia, are reported.

Resistance of certain varieties of apple trees to injury by the leafhopper *Empoasca fabae*, W. J. SCHOENE and G. W. UNDERHILL (*Virginia Sta. Tech. Bul.* 59 (1937), pp. 16, figs. 9).—Following a brief introduction and review of the history of the leafhopper *E. fabae*, officially known as the potato leafhopper and a serious pest of apple foliage, presented in connection with a list of 23 references to the literature, a study of the pest on apple foliage commenced in 1927 is reported.

It was observed that the injury by this leafhopper in 1927 was confined to the tender growing tips both on bearing trees and on nursery stock, and that the different varieties of nursery stock did not show the same degree of leaf curl, those having the most succulent foliage being most seriously curled. Severe injury to foliage was observed to occur over the period from May 20 to July 1. Although the leafhoppers continued to feed throughout the remainder of the growing season, they were found to be present in smaller numbers. It was found at Richmond that the adults occurred on nursery apple trees from April 15 until frost.

When large plantings of apple varieties in parallel rows were studied, some varieties of apple trees were found much more seriously injured than others. The leaf curl was very pronounced on the Early Harvest, Yellow Transparent, and Albemarle Pippin varieties and almost absent on Stayman Winesap, Winesap, and Jonathan. Altogether 58 varieties of apples have been studied and classified according to their susceptibility to leafhopper injury.

Evidently the leafhopper is not equally injurious to all varieties of plants on which it feeds, but the differences in degree of injury produced are less marked when the insects are very numerous. In the different years these observations were made there was some variation in the number of leafhoppers and also the amount of injury, but the range in injury was fairly consistent.

The susceptibility of apple varieties to leafhopper injury varied inversely with the amount of pubescence of the foliage. Varieties of apples having foliage with scant pubescence were subject to serious leaf curl. The varieties which had leaves with dense pubescence were curled only slightly or not at all.

The beet leafhopper in the central Columbia River breeding area, O. A. HILLS (*Jour. Agr. Res. [U. S.], 55 (1937), No. 1, pp. 21-31, figs. 7*).—The limited production of sugar beets due to the prevalence of curly top disease, transmitted by the beet leafhopper, in the Yakima Valley, a potential sugar beet-producing area, led to beet leafhopper surveys by the U. S. D. A. Bureau of Entomology and Plant Quarantine in the breeding area of the central Columbia Valley in south-central Washington and northeastern Oregon, from which populations are dispersed to the Yakima Valley and other surrounding territory.

Three broods of beet leafhoppers were found in this area, for which tumble-mustard, alfalfa, and Russian-thistle serve as the most important host plants. It was found that "the leafhopper usually disperses from this breeding area between May 20 and June 30, movements being more or less continuous during this period. Return to the fall and winter hosts, tumbled mustard and alfalfa, occurs during October and is largely a forced movement caused by the drying of the summer hosts, principally Russian-thistle. If germination of the fall hosts is delayed by drought until after Russian-thistle has dried, a high mortality is likely to result.

High percentages of curly top are directly correlated with large spring-brood populations of the leafhopper. Large populations of the summer and fall broods are relatively unimportant in this respect, except as they affect the magnitude of the spring brood the following year.

"Winter mortality is usually of comparatively little importance in this area. In only one winter of the four observed was there severe mortality, and this was due to subzero weather without snow cover, which not only subjected the insects to intense cold but killed their food plants as well.

"Seasonal variations in color patterns of the beet leafhopper have been observed in this area. In general, dark forms predominate during winter, greenish forms during spring, and straw-colored forms during summer."

Two mealybugs of the genus *Puto* attacking citrus, S. E. FLANDERS (*Pan-Pacific Ent., 12 (1936), No. 4, pp. 196, 197*).—The occurrence of *P. yuccae* Coq. on roots of young citrus trees in Ventura County, Calif., is reported, and notes are given on a species, probably *P. spinosus*, found on citrus in Australia and India.

Control of the mealy plum aphid, L. M. SMITH (*California Sta. Bul. 608 (1937), pp. 34, figs. 12*).—A study of the control of the mealy plum aphid conducted in Placer County on table fruit varieties of plums and in San Joaquin County on drying or prune varieties, commenced in 1928 and continued through 1935, is reported. Studies by the author relating to the biology of this pest have been noted (*E. S. R., 76, p. 507; 77, p. 364*).

This aphid spends the spring and early summer on the plum and the fall on the cattail and reedgrass, with a return migration to the plum occurring in the fall followed by overwintering eggs laid on the trees. Its injury consists of curling and stunting of foliage, lessened growth of new wood, soiling of the bloom of plums, and splitting of the fruit. The elimination of secondary hosts was found to be impractical for areas less than 30 miles in diameter.

"Fall defoliation with leaf-killing sprays was found to be undependable and dangerous to the tree. Tests of single sprays of petroleum oil or soap, with or without nicotine, during the fall, winter, and spring failed to produce a satis-

factory control. Tests of multiple applications of petroleum oil or soap indicated that as many as three applications fail to give a complete kill. Earlier applications of spring sprays gave better results than later spring sprays, and spring sprays showed greater efficiency than fall sprays. The addition of nicotine increased the control to such an extent as to justify its use on a cost basis. Laboratory tests of petroleum oil showed a low kill of eggs, as was likewise the case in the field. Viscosity and unsulfonatable residue were not related to toxicity. Miscible petroleum oil emulsions were not more toxic than paste types. An increase of petroleum oil in the diluted spray resulted in an increase in kill of eggs. Of several materials added to petroleum oil, dinitro-orthocresol, a coal-tar product, gave by far the greatest increase in toxicity. A laboratory test of coal-tar distillate emulsion gave a high kill of eggs. Field tests of winter applications of coal-tar distillate in comparison to spring applications of oil and nicotine demonstrated a greater efficiency for coal-tar distillate. Tests in the field during the dormant period with five miscible and five paste type coal-tar distillate emulsions indicated that the paste type is more efficient. Laboratory tests corroborated this fact. Field tests of tar at five concentrations ranging from 0.5 to 4 percent indicated that 1.5 percent yields a good control when very efficient spraying is done, and that 2 percent is necessary for mediocre spraying. No injury has been done to the trees by tar sprays in any of the experiments reported herein. Increased tree growth follows an application of tar sprays, believed to be the result of absence of aphids. Tar sprays are caustic to men, and sprayers must protect themselves."

Notes on two new oriental parasites of the coffee mealy-bug *Pseudococcus lilacinus*, C. FERRIERE (*Bul. Ent. Res.*, 28 (1937), No. 2, pp. 315-320, figs. 2).—*Pseudaphycus orientalis* and *Anagyrus lilacini*, parasites of the coffee mealybug *Pseudococcus lilacinus* in the Philippine Islands, are described as new.

Moisture as the factor affecting wing development in the citrus aphid *Toxoptera aurantii* Boy., E. RIVNAY (*Bul. Ent. Res.*, 28 (1937), No. 2, pp. 173-179).—The author, in work at the Agricultural Research Station at Rehovoth, Palestine, found that temperature does not affect wing development in the black citrus aphid. A great percentage of aphids developed wings when they were crowded, or when they were forced to feed on stale or wilted food. This was due to the small amount of food and particularly of water which each individual aphid obtained. A reduced percentage of water in the food of aphids, as well as a low atmospheric humidity, are primary factors causing wing development. All the factors such as light, temperature, crowding, humidity, precipitation, growth of plant, etc., exert, directly or indirectly, an influence on the water balance in the body of the aphid, which in turn causes wing development.

Control of oyster-shell scale on apple by means of tar oils, tar-lubricating oils, and lubricating oils containing dinitro-o-cyclohexylphenol, F. Z. HARTZELL and J. B. MOORE (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 651-655).—The experiments at the New York State Experiment Station here reported indicate that "coal-tar oil emulsions, when used at not less than 4.5 percent of tar oil, are of value in the control of the oystershell scale on apple and that the efficiency is increased by the addition of 1 percent of lubricating oil. Also that lubricating oil in which has been dissolved about 4 percent of dinitro-o-cyclohexylphenol will give excellent control of the insect if the oil content of the spray mixture is not less than 4 percent. Water-gas tar oil cannot be regarded from these tests as being of much value for the control of oyster-shell scale on apple unless lubricating oil is added, and even then the results do not equal those secured with coal-tar oil or with lubricating oil containing dinitro-o-cyclohexylphenol.

"Like tar oils, dinitro-*o*-cyclohexylphenol in oil must be applied before the silver-tip stage of the apple buds has been reached if injury to the latter is to be avoided. With all the mixtures practically no injury occurred to apple buds sprayed while dormant in the spring; that is, before the green-tip stage, provided the oils were well emulsified."

The life cycle and seasonal history of *Ceroplastes rubens*, B. BLUMBERG (*Roy. Soc. Queensland, Proc.*, 46 (1934), pp. 18-32, pl. 1, figs. 6).—This contribution on the scale pest *C. rubens* Mask., originally described from Australia and now a common citrus pest throughout coastal Queensland (where it is thought to have been introduced from Ceylon and from there spread to Japan and the Hawaiian Islands), reports upon the life cycle of the female, its seasonal history, and miscellaneous observations, including its parasites and predators.

Control of cabbage worms, H. G. WALKER and L. D. ANDERSON (*Virginia Truck Sta. Bul.* 93 (1936), pp. 1379-1394, fig. 1).—Report is made of control studies with green cabbage worms representing three species, namely, the diamondback moth, which caused heavy losses during the past 5 yr.; the cabbage looper, also very destructive; and the imported cabbage worm, which caused occasional damage. All of these are important enemies of cole crops, and the cabbage webworm was injurious to young cabbage plants in the vicinity of Norfolk in the late summer and fall of 1932.

"Repeated applications of derris and cube dusts containing from 0.5 to 0.75 percent rotenone and from 2 to 3 percent total extractives, and pyrethrum dusts containing from 0.3 to 0.5 percent pyrethrins have given good control of these cabbage worms, while dusts of weaker concentrations of rotenone and pyrethrins were less effective. Also, certain arsenical dusts have given good control, but they should be used only early in the growing season because of the residue hazard. Derris and cube dusts having approximately the same rotenone and total ether extractive content appeared to be about equally effective for the control of these pests. Talc, finely ground tobacco dust, finely ground clay, finely ground dusting sulfur, and dusting gypsum proved to be satisfactory diluents for derris, cube, and pyrethrum powder, but strongly alkaline materials, such as hydrated lime, should not be used in combination with these powders because alkaline substances have a tendency to break down their toxic properties. A mixture of one part by weight of paris green to five parts of lead arsenate gave promising results for the control of the cabbage webworm."

The hymenopterous parasite *Angitia hellulae* frequently parasitizes over 90 percent of the larvae of the diamondback moth, but it has not prevented this pest from causing heavy losses each year for the past 5 yr.

The twig girdler moth of Australian nut trees, C. R. WALLACE (*Agr. Gaz. N. S. Wales*, 47 (1936), No. 10, pp. 566-568, figs. 3).—This is a report on the xyloretid moth *Xylorycta luteotactella* (Walk.), the larvae of which damage nut trees (*Macadamia ternifolia* and *M. integrifolia*) on the north coast of New South Wales, (1) through eating the bark at the axils and finally girdling the twig and (2) by destroying the leaf tissue, frequently skeletonizing the basal halves of the leaves.

Orchard experiments with natural cryolite for codling moth control, I. D. DOBOSCKY (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 656-658).—It is concluded from the experiments conducted that, since both the arsenic trioxide and the fluorine residues are below the tolerance limit, a spray schedule consisting of four lead arsenate sprays and two natural cryolite sprays would be the solution to the residue problem as well as that of codling moth control.

The oriental peach moth in Virginia apple and peach orchards, W. J. SCHOENE, L. R. CAGLE, M. L. BOBB, and R. N. JEFFERSON (*Virginia Sta. Bul. 308* (1937), pp. 23, figs. 17).—Data obtained in studies with bait pails in orchards containing both apple and peach trees near Roanoke during the years 1929–36, inclusive, are reported. Bait pails were also placed in orchards containing only apple trees. It was always possible to collect adults of the oriental fruit moth in apple orchards, but no very great injury to the fruit of winter varieties was observed. While the insect can subsist in orchards with apple as the only food, it is believed that the small size of the fruit at the time when the first brood larvae are hatching serves as an annual check. This was indicated by the small number of moths caught in apples during the first brood in contrast with the much larger number caught during the spring brood. That the small number of moths that survive are able to build up to considerable numbers before harvest was evident in all collections.

"The large number of moths caught throughout the season in apple orchards adjacent to peaches in contrast with the small number caught in apple orchards some distance from peaches indicates that the moth population in apples is increased by the presence of peaches. In orchards containing both apples and peaches the greatest catch of moths during the spring brood was always made in pails near the dividing line between apple and peach orchards, whereas, during the first and second broods, the insects were decidedly more abundant in the peach orchard, only a few moths being caught in apples except in those trees near the peaches. It seems apparent that the increase in the catch of moths in the pails in peach trees next to the apple orchard in the spring was brought about by moths that had developed from larvae that had overwintered in the apple orchard.

"It is concluded as a result of this study that the peach moth can inflict very serious injury to the peach crop when the conditions are favorable for the development of the insect, but that in many years the dry weather in early summer causes the hardening of the twigs, reducing the number of larvae with a consequent reduction of injury to the peach fruit. No serious injury to apple twigs or fruit was observed, although the moths were caught each year in considerable numbers in bait pails exposed in apple trees. The apple supplies food for the larvae in the fall when there are no peaches and when peach twigs are not suitable for food. The data indicate that when apples and peaches are adjacent to each other, the moth population is greater than it is when the two fruits stand alone.

"The practice of planting peach trees and apple trees in the same orchard, so common in Virginia some years ago, created conditions that were especially favorable to the peach moth. This practice has largely been discontinued because the two fruits require different spray treatments. Whenever possible, new plantings of apple trees or peach trees should be made at some distance from older plantings. The observations reported in this bulletin indicate that keeping the new plantings of peaches a few yards distant from older established plantings will tend to discourage the peach moth and reduce its damage.

"Past experience in Virginia indicates that it is practically impossible to grow profitable crops of late varieties of peaches, and that varieties that mature later than the Elberta should not be planted."

Homaledra sabalella Chambers, the major pest of palms in Florida, J. T. CREIGHTON (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 590–595, figs. 2).—A study of the palm leaf miner *H. sabalella*, which attacks many varieties of palms and palmettos, decreasing their value for decorative purposes in Florida, is reported upon. The larvae of this lepidopteran, which live in

colonies of from 35 to 100, are a source of injury to trees of the family Palmaceae only. Its natural enemies include a coleopterous predator *Plochinomus amandus* Newm., which is found extensively in the Gainesville area, and six hymenopterous parasites, which have been found attacking the pest in Florida, namely, *Cryptieropsis orbis* Say, *Apanteles* sp., *Horismenus* n. sp., *Eupelmus limneriae* How., *Bassus difficilis* Mues., and *Macrocentrus* sp.

The cotton web-spinner, W. J. S. SLOAN (*Queensland Agr. Jour.*, 46 (1936), No. 6, pp. 718-728, figs. 4).—*Lowostege affinitalis* Led., which came to attention in the Callide Valley of Queensland 5 yr. previously, but the first outbreak of which took place in the season 1935-36 and was confined mainly to the Callide and Dawson Valleys, is reported upon.

The overwintering of the larvae of *Tortrix postvittana* Walk. in apple orchards, J. W. EVANS (*Jour. Austral. Inst. Agr. Sci.*, 2 (1936), No. 4, pp. 169, 170).—Notes are presented on the light brown apple moth *T. postvittana*, a species indigenous to Australia, where it is seldom of serious economic importance. It is responsible for a considerable amount of damage to fruit in certain apple-growing districts of Tasmania, and has been introduced into New Zealand.

Seek effective control of corn ear worm, L. A. CARRUTH (*Farm Res. [New York State Sta.]*, 3 (1937), No. 4, pp. 6, 14, figs. 4).—A brief account is given of the progress of control work with the corn earworm (particularly through clipping the silks) now being conducted on Long Island, where in the section centered near Roslyn it may infest more than 75 percent of the sweet corn during the latter part of the growing season.

An account by Carruth and Kerr, Jr., of the reaction of this pest to light traps has been noted (*El. S. R.*, 77, p. 369).

Gall-midges (Cecidomyiidae) whose larvae attack fungi, J. A. T. ANDERSON (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 38 (1936), pp. 95-107).—This coordination of the present knowledge of the gall midges (Cecidomyiidae) of the world whose larvae feed on, or are associated with, fungi, contributed from the Rothamsted Experimental Station, includes a systematic list of the fungi attacked by larvae.

Almond and peach buds attacked by a gall midge in Grecco, H. F. BARNES (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 38 (1936), pp. 75-77, fig. 1).—A detailed description is given of a gall midge attacking almond and peach buds at Attica that should be known as *Odinadiplosis (Cecidomyia) amygdali* (Anagnos.).

Sheep blowfly investigations: The effect of trapping on the incidence of strike in sheep, I. M. MACKERRAS, M. E. FULLER, K. M. AUSTIN, and E. H. B. LEFFROY (*Jour. Council Sci. and Indus. Res. [Austral.]*, 9 (1936), No. 3, pp. 153-162, figs. 2).—These experiments have demonstrated that intensive trapping of blowflies decidedly reduces the incidence of strike in sheep. No attempt was made to determine whether trapping is an economical method.

Outbreaks of *Stomoxys calcitrans* L. ("dog flies") along Florida's northwest coast, W. V. KING and L. G. LENERT (*Fla. Ent.*, 19 (1936), No. 3, pp. 33-39, figs. 3).—An investigation is reported of the source of swarms of the stablefly, known locally as "dog fly," that begin to appear as a rule during the latter part of August or first part of September and infest parts or all of the 200-mile section of the Gulf coast forming the southern boundary of the western arm of Florida and extending approximately from Carrabelle on the east to Pensacola Beach on the west. The pest has been found by the authors to develop in accumulated piles of *Sargassum*, probably *S. filipendula* and *S. pteropleuron*, known locally by various names and more generally as gulfweed, that are found in wet swales and at the edge of water with a salt

content of 2.5 percent or perhaps higher. Appearing at times in enormous numbers, the flies are responsible for the closing of beach resorts during the fly period of 2 mo. or more. Livestock, particularly cattle, suffer intensely from their attacks. Fishermen are greatly plagued, and their sudden appearance many miles from shore is said to be a common occurrence. Flies from the coast apparently migrate inland for from 10 to 15 miles or possibly as far as 25 miles in the worst seasons.

On the life history and the biology of the rat-flea (*Nosopsyllus fasciatus* (Bosc.)), M. SHARIF (*Parasitology*, 29 (1937), No. 2, pp. 225-238).—Following a brief summary of earlier work on the rat flea, studies on its biology, particularly the nutritional requirements of the larva, details of which are given in tables, are reported. A list is given of 24 references to the literature.

Progress of Japanese beetle suppression in St. Louis, J. C. DAWSON (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 611-614).—In reporting upon the control work with the Japanese beetle, conducted in St. Louis during the past 3 yr., the results of trapping in 1936 are said to have shown such activities to have been quite successful.

White grub devastations in Iowa nurseries, F. ANDRE (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 615-618, figs. 2).—Contributing from the Iowa Experiment Station, white grubs, which each year damage numerous pastures and various cultivated crops, are said to cause some occasional damage to nursery stock, such infestation having been unusually heavy in nurseries in 1936. In the rearings during that year, of more than 800 larvae secured from the various nursery plantings, 465 reached the adult stage, all of which proved to be *Phyllophaga implicita* (Horn).

White grub damage to pastures on the Atherton Tableland, J. H. SMITH (*Queensland Agr. Jour.*, 46 (1936), No. 4, pp. 446-467, figs. 3).—The scarabaeid *Lepidota caudata* has been a serious pest of pastures in the Malanda district of Queensland and is the most destructive pasture species in the State. Its white grub activity has been confined to the most acid soils.

Investigations of the natural enemies of the Colorado potato beetle in America [trans. title], J. BRUNETEAU (*Ann. Épiphyt. et Phytogénét.*, n. ser., 3 (1937), No. 1, pp. 118-135, figs. 14).—The collection and rearing of the natural enemies of the Colorado potato beetle and their introduction into France from the United States by the author in 1933 are first reviewed. This is followed by a report of observations while engaged in work relating particularly to *Lebia grandis* Hentz, *L. atriventris* Say, *Perillus bioculatus* Fab., *Podisus maculiventris* Say, *Doryphorophaga doryphorae* Riley, and *D. aberrans* Town., with notes on other predators and on secondary parasites.

The biological control of an insect in Fiji: An account of the coconut leaf-mining beetle and its parasite complex, T. H. C. TAYLOR (*London: Imp. Inst. Ent.*, 1937, pp. X+11-239, pls. 23, figs. [19]).—The introduction of natural enemies, particularly the eulopid parasite *Pleurotropis parvulus* Ferr., into Fiji from Java and their control of the serious leaf-mining beetle (*Promecotheca reichel* Baly) enemy of the leaf of the coconut palm is reported upon. Following a brief introduction, a detailed account is given of the history of this hispid beetle and its parasite and predator enemies in Fiji prior to 1933, of *P. reichel* as an insect of economic importance prior to 1933, the nature and extent of control exercised by parasites and other factors prior to 1933, the search for parasites for its control, the hispids and parasites concerned and the selection of parasites, of *Pleurotropis parvulus*, introduction into Fiji of parasites from Java and the consequent control of *Promecotheca reichel*, and methods employed for breeding and studying *Promecotheca* and its parasites and for collecting data in the field.

P. reichei is the third coconut pest to be controlled in Fiji through the introduction of natural enemies, the zygaenid moth *Levuana iridescens* B. B., a serious menace to the coconut industry in Fiji, having been completely suppressed by the tachinid parasite *Ptychomyia remota* Ald. (E. S. R., 64, p. 460) introduced from Malaya, and the coconut scale *Aspidiotus destructor* Sign. by the coccinellid beetle *Cryptognatha nodiceps* Sic. introduced from Trinidad (E. S. R., 73, p. 353).

A list of 28 references to the literature is included.

Blapstinus substriatus Champion, a sporadic wheat pest in Montana, G. A. MAIL (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 670-675, fig. 1).—Observations of the beetle *B. substriatus*, which is normally present every year in small numbers over a wide area of the State, are contributed from the Montana Experiment Station. "Dry weather conditions with an absence of precipitation in the spring would appear to insure optimum conditions for an increase of this beetle to outbreak proportions. Following the heavy spring rains of 1932 no further trouble was experienced from this pest in areas severely attacked during the previous year. The wide distribution of this beetle and its general feeding habits render it, therefore, a potential source of trouble should climatic conditions at any time favor its increase. Under field conditions standard poisoned bran mixtures were effective in controlling this pest."

A note on the reduction in the fecundity of *Tribolium confusum* due to eating its own eggs, J. STANLEY (*Canad. Jour. Res.*, 15 (1937), No. 5, Sect. D, p. 111).—This note supplements the contribution previously noted (E. S. R., 68, p. 359).

Effect of growth of pea weevil on weight and germination of seed peas, T. A. BRINDLEY and F. G. HINMAN (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 644-670, figs. 6).—The authors have found that "the loss in weight and viability of weevil-infested peas is correlated with the development of the pea weevil, and therefore increases rapidly with each successive day until the larvae within them have finished feeding. During some seasons 100-percent weevil-infested peas, when fumigated as soon as they ripen, will germinate nearly as well as sound peas. Weight loss in 100-percent weevil-infested Alaska peas may be as high as 22.4 percent, in comparison with 1.1 percent weight loss in sound peas."

The vetch bruchid (*Bruchus brachialis* Fahraeus), J. S. PINCKNEY (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 621-632, figs. 3).—The vetch bruchid, which is widely distributed in Europe, Algeria, and Anatolia (Asia Minor), was first discovered in the United States on June 24, 1930, at Haddon Heights, N. J., by Bottimer (E. S. R., 69, p. 696). Since that time it has spread, and now occurs in the South Atlantic States as far south as Georgia. Its importance as a pest of vetch seed has been demonstrated by the recent heavy losses resulting from its attacks. "This insect has one generation a year and does not breed in dried seed. The eggs are laid on the green pods in the spring. The larvae feed within the seed and complete their development there. The adults emerge during summer. The hibernation habits of the species are unknown. There appears to be wide variation in the susceptibility to attack by the bruchid of the various species of vetch, the smooth and hairy varieties of *Vicia villosa* being most generally and most severely infested.

"The greatest danger of transportation out of the infested area lies in the shipment of vetch hay and in the movement of seed before all the beetles are dead in the seeds and sacks. Interception of living beetles in commercial shipments from Europe in 1936 indicates that fumigation of the seed will

be necessary for all shipments. Fumigation with hydrocyanic acid gas, both under vacuum and at atmospheric pressure, was found to be effective. The effectiveness of carbon disulfide as a fumigant for the adult vetch bruchid was indicated. Viability of vetch seed apparently was not reduced by fumigation with hydrocyanic acid gas."

Notes on the ecology and control of pine beetles in Great Britain, H. S. HANSON (*Bul. Ent. Res.*, 28 (1937), No. 2, pp. 185-242, pls. 3, figs. 8).—This contribution considers the economic status of pine beetles, particularly *Myelophilus piniperda*, in Great Britain, with an analysis of damage, and reports upon the occurrence of outbreaks, factors influencing the pine beetle population, and silvicultural treatment and forest hygiene.

The introduction from Fiji into Puerto Rico of a predator of the banana corm weevil, K. A. BARTLETT (*Puerto Rico Sta. Agr. Notes* No. 79 (1937), pp. 3).—The successful introduction from Fiji of the histerid predatory beetle *Plaesius javanus* Arr., the only known effective natural enemy of the banana root borer, is recorded. A total of 537 individuals have been liberated on the island.

Three weevils of the genus *Rhynchites* injurious to fruit, S. W. ROLFE (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 38 (1936), pp. 86-94, figs. 9).—Notes are given on three weevils that have been recorded during recent years attacking fruit, namely, the apple twig cutter *R. cocculeus* DeG., the strawberry leaf cutter *R. germanicus* Hbst., and *R. aequatus* L.

The Queensland pine beetle and its control, A. R. BRIMBLECOMBE (*Queensland Agr. Jour.*, 46 (1936), No. 5, pp. 582-585, pl. 1).—The ptnid borer *Calymma-derus incisus* Lea, a pest of major importance to homeowners in southeastern Queensland but which confines its damage entirely to hoop pine, is reported upon.

Beekeeping (*Alaska Sta. Bul.* 6 [1937], pp. 22-24, fig. 1).—Reference is made to honey production, tables being given which show the daily weights of hives at the station over the 30-day period from July 25 to August 24, 1936.

The influence of colony populations on honey production, C. L. FARRAR (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 12, pp. 945-954, fig. 1).—In this contribution the author outlines a method for analyzing the influence of colony populations on production and reports upon the preliminary results of studies of this relationship carried on by the Intermountain States Bee Culture Field Laboratory, at Laramie, Wyo.

"A high correlation and a linear relationship were found to exist between the populations of small groups of colonies and their respective productions during periods of less than 2 weeks when all colonies had access to the same source of nectar for the same period of time. The production level varied between seasonal or locality segmental groups of colonies owing to differences in the amount of nectar available, but the relative production slopes of 16 segments when reduced to standard production factors per unit of bees were found to be fairly similar."

A method was developed for standardizing segmental population-production data to a standard honey-flow level by averaging the actual regression lines of the segmental data.

The conclusion is drawn from the production factors derived that the production efficiency of colonies increases as the population increases throughout the normal population range of 15,000 to 60,000 bees.

Relation of size to fecundity in queen honeybees, J. E. ECKERT (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 646-648).—The results of studies reported indicate "that the body measurements of the queen that were studied cannot be

used as criteria of fecundity. The results are of further significance in that they indicate but little correlation between the development of the external parts and of the internal characters studied. Evidently, therefore, other factors must be included with these values in future studies of this problem. Our studies would justify the suggestion that one might find a definite correlation between such characters as external size and the total development of the ovaries in queen honeybees if one could gauge accurately the size of ovaries by their length or weight as well as by the number of ovarioles. These factors are influenced by many physiological conditions as well as by unmeasurable environmental entities. The use of a greater number of individuals in determining the relation between the size of ovary and brood production and the use of an average of a series of brood counts over a longer period might be expected to smooth out certain errors that are magnified in importance when one is dealing with the number available in the present studies."

Further contribution to the study of pollen substitutes, M. H. HAYDAK (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 637-642, fig. 1).—In continuation of work at the Minnesota Experiment Station (E. S. R., 76, p. 369), it was found that "bees can develop their bodies normally when fed soybean flour, soybean meal, peanut meal, linseed meal, or soybean meal, linseed meal, and cottonseed meal, each mixed with powdered skim milk, 20 percent by weight. The lowest mortality was observed in the linseed meal-fed colony, the highest in that which had soybean meal for food. The behavior was normal in all the experimental colonies. Only those colonies which had pollen, soybean flour, soybean meal, or cottonseed meal, [the last two] mixed with skim milk powder, produced young bees. The largest number was reared by the control colony. The young bees produced by the colonies which reared brood were normal, but those produced by the soybean meal-skin milk powder-fed colony had the lowest weight and nitrogen content. Building activity was normal in all the colonies."

Alleged vitamin E content in royal jelly, H. M. EVANS, G. A. EMERSON, and J. E. ECKERT (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 642-646).—Data presented in three tables failed to show vitamin E activity when royal jelly, its fat-soluble fraction, or pollen from the comb was fed to young female rats of proved sterility. The results are considered highly significant, since the quantities of royal jelly fed were far greater than previously reported by other workers.

Preliminary report on American foulbrood, R. S. FILMER (*Jour. Econ. Ent.*, 30 (1937), No. 4, pp. 634-637).—Reference is made to the progress of research work by the New Jersey Experiment Stations (1) in an effort to find colonies of bees which exhibit some degree of resistance to infection by American foulbrood and (2) for a more efficient method for sterilizing infected equipment.

The results show that "radio frequency oscillations of the nature used in these experiments are not lethal to the spores of *Bacillus larvae* when scales of larvae dead from American foulbrood are treated for various time intervals. It was found in this study that the time intervals could not be greatly increased because of a tendency for the scale material to heat rapidly which caused it to char and burn. In all cases where the exposure time was less than 60 sec. the scale material was ignited and was removed for testing before it was destroyed. The rapid heating of the scale material by radio frequency oscillations used in this experiment would prevent its use as a sterilizing agent for infected comb material."

The citrus gall wasp *Eurytoma fellis* Girault, N. S. NOBLE (*N. S. Wales Dept. Agr., Sci. Bul. 53* (1936), pp. 41, figs. 18).—A study of the morphology, biology, etc., of *E. fellis*, which causes severe galling of citrus on the north coast of New South Wales, is reported upon.

The introduction and colonization in Puerto Rico of *Macrocentrus ancylicivorus*, K. A. BARTLETT (*Puerto Rico Sta. Agr. Notes No. 80* (1937), pp. 4).—The introduction and release of 7,284 oriental fruit moth parasites (*M. ancylicivorus*) from the United States as a means of control of the lima bean pod borer and/or related borers (*Maruca testulalis* Geyer and *Fundella cistipennis* Dyar) are reported.

Euplectrus agaristae Crawford, a parasite of the grape vine moth *Phalaenoides glycinae* Lew., N. S. NOBLE (*Jour. Austral. Inst. Agr. Sci., 2* (1936), No. 4, pp. 165-168, figs. 2).—A study of the biology of the eulophid chalcidoid *E. agaristae*, the larvae of which are gregarious external parasites of the larvae of the grapevine moth *P. glycinae*, a common pest of the grapevine in New South Wales, is reported. The average length of life of 271 individuals in the laboratory was 49.78 days, with a minimum of 6 days and a maximum of 187 days. The fact that the parasite larva feeds externally on a host larva which is itself feeding externally and is not paralyzed prior to parasitization is unusual, as is also the construction of a cocoon by a chalcid larva and the secretion of the silk from the Malpighian tubes through the anus of the larva.

Notes on the life-history of *Eriophyes carinatus* Green, C. B. REDMAN KING (*Bul. Ent. Res., 28* (1937), No. 2, pp. 311-314).—Notes are presented on *E. carinatus*, commonly known in Ceylon as purple mite, which also occurs in north India and Java but has not become sufficiently important as a tea pest to require artificial control measures.

ANIMAL PRODUCTION

[Livestock investigations in Alaska], D. L. IBWIN (*Alaska Sta. Bul. 6* [1936], pp. 13-15, 25, fig. 1).—Information is presented on the performance of foundation herds of Rambouillet sheep and Guernsey cattle at the Matanuska Substation.

[Livestock investigations in Idaho], H. P. MAGNUSON, C. W. HICKMAN, R. F. JOHNSON, J. TOEVS, and C. E. LAMPMAN (*Idaho Sta. Bul. 221* (1937), pp. 8, 9, 20-22, 23, 24, 25, 42, 43, 45, 48, 49, 50-53).—Beef cattle studies reported include phosphorus deficiencies in different sections of the State, the negative response of fattening steers to phosphorus supplements in a ration, and at the Caldwell Substation wheat bran v. oats with barley for fattening calves, and feeding yearling steers on pasture.

The results of sheep studies are noted on the response of fattening lambs to phosphorus supplements in the ration, the occurrence of overshot and undershot jaws in sheep, artificial insemination of ewes, and from the Caldwell and Aberdeen Substations on wintering ewes and spring lamb production, cottonseed meal v. bonemeal as sources of phosphorus for lambs, deferred grain feeding for fattening lambs, the relative gains of yearling wethers v. lambs, and shearing feed lot lambs. The inheritance of inverted nipples in swine has been studied.

Poultry tests gave information on the vitamin A requirements of laying hens, the relative protein requirements of turkeys and chickens, and the artificial incubation of pheasant eggs.

The carotene content of dehydrated alfalfa products is noted.

[Livestock investigations in Kentucky] (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 14-18, 36, 37, 47, 48, 52, 53*).—Among the studies discussed are cottonseed meal v. distillers' dried grains for fattening steers; distillery slop for hogs; a comparison of oats and rape, bluegrass, alfalfa, and lespedeza pastures for hogs; roughages for breeding ewes in winter and spring; the chemical composition of several grasses, lespedeza, alfalfa, red clover, and corn; comparative returns from continuous v. alternate grazing of permanent pastures with heifers, and the nutrient content of canned dog feeds.

Poultry experiments reported include protein levels for pullets, Kentucky bluegrass as a source of protein for growing chicks, lespedeza byproducts and distillery byproducts for feeding chickens, turkey incubation studies, the use of laying mash for chicks, and the cholesterol content of fresh and storage egg yolks.

[Investigations with livestock in Massachusetts] (*Massachusetts Sta. Bul. 339 (1937), pp. 21, 22, 85, 86, 87*).—Brief results are reported on the relation of birth weight to vitality and growth rate in lambs, by R. W. Phillips; and progeny performance in sheep, by C. H. Parsons, R. C. Foley, and J. C. Hillher. From poultry tests results were noted on broodiness in poultry, rate of feathering and breeding for plumage color in Rhode Island Reds, and breeding for low mortality, all by F. A. Hays; breeding for egg production, by Hays and R. Sanborn; and breeding for high and low resistance to fowl paralysis, by Hays, W. C. Sanctuary, and J. H. Vondell.

The time of cutting hay, and the losses entailed during haymaking, S. J. WATSON, W. S. FERGUSON, and E. A. HOBTON (*Jour. Agr. Sci. [England], 27 (1937), No. 2, pp. 224-253*).—This is an extensive report of 6 years' experimentation on the composition, digestibility, and yield of meadow hay cut at a normal time and also at immature stages.

The nutritive value of meadow hay, S. J. WATSON and W. S. FERGUSON (*Jour. Min. Agr. [Gt. Brit.], 44 (1937), No. 3, pp. 247-260*).—Information is presented on the chemical composition, digestibility, and nutritive value of 22 samples of hay collected from 15 counties in Great Britain during 1935. Linear regression equations are presented whereby the protein equivalent value may be estimated from the crude protein content of a given feed and the starch equivalent estimated from a combination of the crude fiber and crude protein contents.

Grass silage: A comparison of the changes involved in the ordinary, molasses, and A. I. V. processes, W. M. DAVIES, G. H. BOTHAM, and W. B. THOMPSON (*Jour. Agr. Sci. [England], 27 (1937), No. 2, pp. 151-161*).—Results obtained at the Harper Adams Agricultural College are presented on the palatability and keeping quality, composition, digestibility, and losses in grass silages prepared in the ordinary method and with additions of molasses or mineral acids (A. I. V. process).

All silages seemed quite palatable to cattle, but the A. I. V. proved less palatable than the others for sheep. Digestibility, based on dry matter content, was highest for the A. I. V. silage and lowest for the ordinary silage. Losses of crude dry matter during ensiling were lowest in the molasses lot, highest in the ordinary, with A. I. V. intermediate, while losses of digestible nutrients, starch equivalent, and true protein were lowest in the A. I. V. and highest in the ordinary silage. From the standpoint of applicability to farm practice the molasses process is the most highly recommended.

A study of the chemical and bacteriological changes occurring in grass silage, L. A. ALLEN, J. HARRISON, S. J. WATSON, and W. S. FERGUSON (*Jour. Agr. Sci. [England], 27 (1937), No. 2, pp. 271-293, figs. 4*).—Results of this study indicate that the chemical changes associated with the fermentation of grass

silage result in a rapid development of acidity which lowers the pH of the mass from approximately 6.5 to between 5.0 and 3.5. Normally acidity is due almost entirely to the development of lactic and acetic acids. Proteolysis occurs at early stages, but is normally checked by the increasing acidity. These changes occur, in the main, during the first 10 days. Coliform bacteria and lactobacilli, particularly the latter, are considered to be mainly responsible for the acid formation. Certain anaerobes may develop after several days, the extent of their development depending upon the residual carbohydrate and protein and the restraining effect of acidity. Micrococci, yeasts, and aerobic spore-formers normally contribute only to a limited extent to the general chemical break-down.

The effect of the addition of various materials and bacterial cultures to grass silage at the time of making on the subsequent bacterial and chemical changes, L. A. ALLEN, S. J. WATSON, and W. S. FERGUSON (*Jour. Agr. Sci. [England]*, 27 (1937), No. 2, pp. 294-308).—As an outgrowth of the above study, trials were conducted in which the effect of adding to grass silage dried whey, fresh whey, solutions of dried whey, and solutions of molasses, each inoculated with lactobacilli, solutions of dried whey alone, and mineral acids was determined. The additions of whey and molasses resulted in a high lactic acid content and the production of silage of excellent quality and digestibility. Fresh whey was less satisfactory than solutions of concentrated or dried whey because of the large amount of water contained in the former and also because of the chance of introducing a large mixed bacterial flora which may develop in a way detrimental to the predominance of lactic acid fermentation. Molasses proved a suitable source of carbohydrates, and subsequent development of lactobacilli may be further insured by inoculating the molasses with a suitable culture.

The nutritive value and mineral deficiencies of soybeans, C. L. SHREWSBURY and C. M. VESTAL (*Indiana Sta. Bul.* 420 (1937), pp. 25).—The results of 10 experiments are reported in which identical rations were fed simultaneously to pigs and rats. In the first four experiments, designed to study the effect of various protein supplements and also a vitamin B supplement on the nutritive value of a basal corn, raw soybeans ration, it was found that the addition of such supplements as tankage, meat scrap, or casein resulted in a marked increase in the growth-promoting properties of the ration. However, such protein supplements apparently corrected the deficiencies of corn, as no evidence was obtained to indicate that the deficiencies of soybeans as a protein supplement to corn could be corrected by adding other proteins to the ration. The corn-soybean ration did not prove to be deficient in vitamin B. Experiments 5 and 6, dealing with the effects of heat treatment on the nutritive value of soybeans, gave evidence that either steaming or roasting the soybeans brought about a change which made them an excellent protein supplement to corn. Experiments 7 to 10 tested the effects of various mineral supplements on the corn-soybean or corn-soybean-casein-yeast ration and also the comparative effects of a ground limestone-superphosphate supplement on rations of corn plus soybeans in the raw, cooked, or roasted condition or soybean oil meal. No mineral mixture produced satisfactory gains on the corn-raw soybean diet, although the bone structure was favorably influenced. With hogs the effect of mineral additions was most pronounced on the roasted soybean ration, although beneficial on all rations. The response of rats to mineral additions was much more marked than for hogs.

Cocoa husks as a feeding stuff [trans. title], K. RICHTER and H. BRÜGEMANN (*Biedermanns Zeitbl., Abt. B, Tierernähr.*, 9 (1937), No. 2, pp. 184-188; *Eng. abs.*, p. 188).—Digestion trials with four wethers in which cocoa husks were

fed as a supplement to meadow grass indicated average digestibility coefficients of 27.4, 34.5, and 82.9 percent for the crude protein, crude fiber, and nitrogen-free extract, respectively, in the husks. True protein proved to be indigestible. A starch value of 53 kg per 100 kg of dry matter is ascribed to the husks.

The feeding value of wood sugar yeast [trans. title], K. RICHTER and H. BRÜGGEMANN (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 2, pp. 95-105; Eng. abs., p. 105*).—Metabolism trials with pigs and wethers indicated that the wood sugar yeast tested contained over 46 percent of digestible crude protein, over 40 percent of digestible pure protein, and starch values in excess of 76 kg per 100 kg of feed. It is concluded that this product should be classed in the series of valuable protein feeding stuffs.

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Circ. 228 (1937), pp. 32, fig. 1*).—This is the condensed report of commercial feed inspection for 1936 (E. S. R., 75, p. 821), including 3,084 samples examined microscopically and 2,864 analyzed chemically.

Commercial feeding stuffs, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul. 416 (1937), pp. 40*).—This is the usual report of the analyses for protein, fat and fiber of 2,216 samples of feeding stuffs collected for official inspection during December 1936 (E. S. R., 76, p. 670).

Interpretation of variations in plant composition in relation to feeding value, L. A. MAYNARD (*Jour. Amer. Soc. Agron., 29 (1937), No. 6, pp. 504-511*).—This is a brief review of the energy, protein, mineral, and vitamin requirements of herbivorous farm animals and the relative efficiency with which different types of plant materials may be expected to meet these requirements.

Recent developments in minerals and vitamins for farm animals, L. A. MAYNARD (*Cornell Vet., 27 (1937), No. 2, pp. 122-129*).—This is a review of recent findings in these important fields of animal nutrition.

Sulphur metabolism, II-IV, J. H. KELLERMANN (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 7 (1936), No. 1, pp. 189-224*).—This series of studies is continued (E. S. R., 75, p. 820).

II. *The distribution of sulphur in the tissues of rats fed rations with and without the addition of elementary sulphur* (pp. 189-197).—The distribution of sulphur in the tissues of three groups of rats is reported. One lot received a control basal diet; the second lot the basal diet plus 0.8 percent of elementary sulfur; and the third lot the basal diet, 0.8 percent of sulfur, and orange juice ad libitum. Sulfur feeding markedly increased the total sulfur content of the lung and spleen and to a lesser extent of the heart and kidney. Slightly less sulfur was stored in the tissues of the group receiving orange juice. The sulfur feeding had little effect on the sulfate content or the concentration of volatile sulfides in the tissues.

III. *The effect of flowers of sulfur on the growth of young rats fed an otherwise well-balanced ration* (pp. 199-207).—The effect of flowers of sulfur on the growth of rats maintained on two types of basal diets, one a low protein diet and the other an optimum diet, was studied. Adding 0.8 percent of sulfur to the low protein diet which was also low in cystine and "food sulfur" caused a marked retardation of growth, while additions of sulfur up to 3.5 percent in the complete diet had little toxic effect. It appears that rations complete in all respects, with optimum levels of protein and food sulfur, possess greater anti-toxic effect to sulfur poisoning than rations which are low in these constituents.

IV. *The oxidation and reduction of elementary sulfur by animal tissues in vitro* (pp. 209-224).—In these studies with various beef tissues it appeared that all protein tissue was capable of reducing sulfur to hydrogen sulfide. Acids

inhibited this reaction, whereas alkalis and alkaline salts enhanced it. Also acids inhibited and alkalis and alkaline buffers increased the oxidation of reduced sulfur to sulfates. Apparently all tissues in the animal organisms should be able to oxidize sulfides.

The minimum vitamin A and carotene requirement of cattle, sheep, and swine, H. R. GUILBERT, R. F. MILLER, and E. H. HUGHES (*Jour. Nutr.*, **13** (1937), No. 5, pp. 543-564).—Supplementing a previous report on the carotene requirements of cattle (E. S. R., **74**, p. 527), information is presented on the requirements of swine and sheep for carotene as supplied by alfalfa hay and by solutions of carotene crystals in cottonseed oil and also on the requirements of cattle, swine, and sheep for vitamin A as supplied in cod-liver oil. The night-blindness test and a check on storage either by depletion or by the antimony trichloride test on extracts of the liver tissue were used as the criterion of sufficiency.

The amount of vitamin A or carotene daily which just prevented night blindness apparently represented a physiological minimum. The minimum carotene requirement was found to be of the same order for these three species, namely, from 25 to 30 μ g daily per kilogram of body weight, and the minimum vitamin A requirement was from 6 to 8 μ g daily per kilogram of body weight for each species. This required level of intake is in close agreement with data on the rat reported from various sources, tending to support the previously expressed hypothesis that the vitamin A requirement of mammals is directly related to body weight rather than to their energy requirements. The data on cattle, sheep, and swine indicated that the minimum levels of carotene intake which prevent night blindness permitted only small storage in the liver, and these levels appeared to be subminimal for normal pregnancy since the calves or lambs from experimental animals were either born dead or were very weak at birth and died soon after. No storage in the livers of these calves or lambs could be demonstrated.

The vitamin content of the seed of blue sweet lupine, strain 411 [trans. title], A. SCHEUNERT and M. SCHIEBLICH (*Biedermanns Zentbl., Abt. B, Tierernähr.*, **8** (1936), No. 1-2, pp. 132-135; *Eng. abs.*, p. 135).—Assay of the seed of an alkaloid-free strain of blue sweet lupine showed 1 g to contain 30 international units of vitamin A and 3 international units of vitamin B₁. The content of B₂ was relatively lower, corresponding to about that of the hay.

Cane molasses versus beet molasses as a source of vitamin B₁ and lactoflavin, P. GRÖGNY (*Soc. Égypt. Biol. and Med. Proc.*, **36** (1937), No. 2, pp. 167-169).—This report, based upon feeding tests with rats, indicates that crude cane molasses is a good source of vitamin B₁ and also contains small amounts of lactoflavin, whereas beet molasses is practically devoid of both of these fractions.

Gastro-intestinal motility in the ruminant, H. H. DUKES and J. SAMPSON (*Cornell Vet.*, **27** (1937), No. 2, pp. 139-149).—The New York State Veterinary College has studied the gastrointestinal motility in anesthetized sheep by the open-abdomen saline-bath method. Limited information could be gained regarding the motility of the rumen, reticulum, and omasum, although certain types of motility of the rumen and reticulum are described which cannot be determined in the fistula method of study. Spontaneous contractions of the omasum were not observed. Good results were obtained on the type of motility of the abomasum and the large intestines and fair results from the small intestines, and these are fully described.

The variation of the nitrogen and ether extract contents in the rumen during digestion, with reference to a possible fat synthesis through action

of the rumen flora [trans. title], F. W. KRZYWANEK and G. QUITTEK (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 1-2, pp. 136-147; *Eng. abs.*, p. 147).—This study was conducted with sheep, employing a rumen fistula technic. The percentage of moisture and also the percentage of nitrogen and crude fiber in the dry matter of the rumen content was found to increase as the length of the digestion period in the rumen increased. Increased moisture was attributed to the constant secretion of the salivary glands, and increased nitrogen and fat in the dry matter resulted mainly from the fermentation of the carbohydrates present. The iodine number of the crude fat in the rumen remained constant during digestion, indicating that no change in fat structure occurred. The ratio of crude fat to nitrogen after 3, 6, and 9 hr. of rumen digestion as compared with their ratio in the ration showed a slightly decreasing ratio with increase in the length of the digestion period. Neither a decrease nor the removal of infusoria from the rumen content caused a reduction in the fat: nitrogen ratio, indicating that the infusoria had little or no influence on the crude fat present.

The effect of different nitrogen-bearing compounds of nonprotein nature (amide) on the nitrogen balance in ruminants: Trials with glyccoll, urea, and ammonium acetate [trans. title], K. NEHRING (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 9 (1937), No. 1, pp. 79-94; *Eng. abs.*, p. 94).—Metabolism trials were conducted with wethers in which one-third of the basal hay ration was replaced by a simple nitrogen-bearing compound and potato flakes, the substitutions being made at such levels as to provide equivalent total nitrogen contents. Data are reported on nitrogen balance, sulfur balance, and the content of different nitrogen fractions in the urine. The nitrogen balance was favorably affected by the presence of amides in the diet. Negative nitrogen balances which occurred during the basal and deficiency feeding periods were changed to positive balances when amides were fed. Ammonium acetate gave most favorable results in this respect, urea gave somewhat less favorable results, and glyccoll was the least effective of the nitrogen compounds tested. In general sulfur balances nearly paralleled the nitrogen balances. These results indicated that a part of the nitrogen in the ration of ruminants may be satisfactorily supplied by simple organic or inorganic nitrogen compounds.

Beef cattle production in the Blackland area of North Carolina, J. E. FOSTER, E. H. HOSTETLER, and L. I. CASE (*North Carolina Sta. Bul.* 310 (1937), pp. 14, figs. 4).—Native and grade Hereford cows and their calves were turned on reed pasture May 1 of each of the three years included in this study. The cows were maintained on this pasture until January 1, then allowed to glean corn and soybean fields until March 15, then grazed on rye pasture and fed corn, cottonseed meal, and native roughage until May 1. The calves were weaned on November 20, wintered on cornstalk gleanings and rye pasture, with limited feeding of cottonseed meal, corn, and native roughage. As yearlings they were grazed on reed and tame pasture from May 1 to November 15, then finished in dry lot on a full feed of corn, cottonseed meal, soybean hay, and corn stover until April 15 when they were disposed of for slaughter. Under this system the net annual cost per cow was calculated to be \$12.60 per year, divided as follows: Winter feed cost 56 percent, labor 12, interest on cattle 11, summer pasture 9, equipment 7, and all other costs 5 percent. Of the average gain of 726 lb. made between the time calves were 2 mo. old and the time they were finished for market approximately 30 percent was made before weaning, 32 percent between weaning and the time they were placed in feed lot, and 38 percent in the feed lot. The average cost per hundredweight of native

weaned calves, yearling stockers, and finished 2-year-olds was \$6.00, \$4.58, and \$6.13, respectively, and for the grade Herefords \$5.64, \$4.30, and \$5.66, respectively.

Other data regarding feed consumption, economy of gain, and market grade of these animals have been previously noted (E. S. R., 77, p. 82).

A grazing adventure in northern Minnesota, M. J. THOMPSON (Duluth: Minn. State Emergency Relief Admin., [1935], pp. [51], figs. 10).—This is an extensive report of the Minnesota S. E. R. A. emergency pasturage project conducted in northern Minnesota from July 23 to December 31, 1934, in which approximately 52,000 head of cattle were moved from the drought area into nine counties in northeastern Minnesota. Statistical records are presented on the number of cattle received, the number and percentage recovered, and causes of losses by herds and by counties, with a comparison of the effectiveness of the various pasture types involved. Discussion includes claims, gains and losses, costs, thievery, local reactions, and permanent values of the project. Included are the conference findings on the emergency pasture survey.

The use of native grass in producing finished cattle, M. L. BAKER (Nebraska Sta. Bul. 307 (1937), pp. 16, figs. 3).—This is a report of a series of steer feeding trials in which full-feeding of steers on alfalfa hay and corn throughout the finishing period was compared with full-feeding, limited feeding, and no feeding of corn to steers on native pasture (average 79 days), each followed by full-feeding of corn and alfalfa in dry lot. At least three trials were conducted with each type of feeding. Steers full-fed on pasture and finished in dry lot made practically the same gains and were of equal market desirability as those full-fed throughout in dry lot. It is indicated that when 1 ton of alfalfa hay is worth more than 5.3 bu. of corn and 8 mo. of pasture for one steer, the pasture-feeding method will yield more economical gains. Steers receiving a limited amount of corn (average 7.74 lb. per head daily) on pasture made definitely cheaper gains than those receiving a full feed (average 14.88 lb.) on pasture, and there was no apparent difference in the market desirability of the two lots. The limited-fed steers required approximately 4 weeks longer feeding than the lot full-fed on pasture. Steers receiving no grain on pasture made cheaper gains and sold as well as those receiving limited grain. However, slaughter data showed that they were not as well finished, and it is suggested that a 6 to 8 weeks longer finishing period would be required to attain the same degree of finish. Since the limited- or no-grain-fed groups required a longer finishing period they make larger total gains and should be lighter in weight at the start of the grazing season if all cattle are to be marketed at approximately the same weight. A chart is presented for estimating the cost of gain under the three systems of feeding on pasture with a range in prices of corn and alfalfa hay.

Nitrogen balance of cattle receiving urea and a urea-potato flakes mixture as protein substitutes [trans. title], E. MANGOLD and H. STOTZ (Landw. Vers. Sta., 127 (1936), No. 1-2, pp. 97-118).—Nitrogen balance trials were conducted with two bull calves on a basal ration of hay and soybean meal and with 25 percent of the digestible proteins in the basal ration replaced by equivalent amounts of nitrogen as urea or as a proprietary mixture of urea and potato flakes. The nitrogen balance was unaltered by substituting urea in the ration and was slightly increased when the urea-potato flake mixture was fed. The food deficiencies of the urea could not be determined from the results of these trials.

Afrikaner cattle: Breed history and Standard of Excellence, T. G. W. REINECKE (Farming in So. Africa, 12 (1937), No. 133, pp. 149-152, figs. 3).—This

article discusses the history and present status of the Africander breed of cattle and sets forth the recently adopted Standard of Excellence.

[Thirteenth and fourteenth annual reports of the activities of the National Live Stock and Meat Board for the fiscal years 1935-36 and 1936-37], R. C. POLLOCK (*Natl. Livestock and Meat Bd. Ann. Rpts.*, 13 (1936), pp. 112, figs. 55; 14 (1937), pp. 112, figs. 58).—These reports (E. S. R., 73, p. 825) contain accounts of investigations on meat nutrition and the quality and palatability of meat, including progress reports of the cooperative meat investigations being conducted by the several State experiment stations and the U. S. Department of Agriculture.

Chilled beef carriage: Preventing ice formation by electricity (*Cold Storage*, 40 (1937), No. 468, p. 65, fig. 1).—This note describes a method for preventing ice formation in chilled beef during transit at 29.5° F. by placing electrodes in the upper and lower ends of each suspended quarter so that electric current from any suitable source may be passed through the quarters. It is stated that beef in transit for 21 days arrived in an entirely satisfactory condition.

Sheep nutrition, I, II, H. E. WOODMAN, R. E. EVANS, and A. EDEN (*Jour. Agr. Sci. [England]*, 27 (1937), No. 2, pp. 191-223).—Two reports are presented from the School of Agriculture, Cambridge.

I. *Measurements of the appetites of sheep on typical winter rations, together with a critical study of the sheep-feeding standards* (pp. 191-211).—In a series of feeding trials with sheep subsisting outdoors on typical winter rations, the appetite of a 100-lb. sheep measured in terms of dry matter intake was found to be slightly over 20 lb. per week. The maintenance requirement is tentatively established at 9 lb. of starch equivalent and 0.38 lb. of digestible protein per week. A summary of the Wood feeding standard for sheep and the authors' revision of it are presented.

II. *Determinations of the amounts of grass consumed by sheep on pasturage of varying quality* (pp. 212-223).—In this phase of the study the feces voided by sheep on pasture were collected in special waterproof bags attached to the hindquarters by a light webbing harness, and weight determinations were made. During the same period the digestibility of the herbage was determined in independent trials with other sheep. With this information the mean daily grass consumption of each sheep was calculated. The results indicate that sheep consume a greater quantity of dry matter when on pasture than when on a typical winter ration, one group consuming from 80 to 88 percent of the amount predicted by the Wood standard on winter rations and from 104 to 117 percent of the predicted amount when on pasture.

Relation of certain dietary essentials to fertility in sheep, G. H. HAFT and R. F. MILLER (*Jour. Agr. Res. [U. S.]*, 55 (1937), No. 1, pp. 47-58).—The California Experiment Station has conducted experiments to determine whether any particular dietary essential is necessary for high fertility in sheep or whether the problem is one merely of total energy intake. During the course of the four trials reported the effect of low vitamin A intake, low protein intake, and low phosphorus intake was studied.

When ewes were in good condition and had large stores of vitamin A in their livers, a low vitamin A intake for 5 mo., including the breeding season, did not significantly reduce the number of lambs born as compared with the control animals receiving vitamin A above minimum requirements during the breeding season. With similar ewes, limiting the protein intake over a 4-mo. period, including the breeding season, had little effect on the number of lambs produced. When ewe lambs were restricted to a low vitamin A in-

take they were not depleted of vitamin A stores at breeding time, but continuation of the deficient diet during gestation led to depletion of vitamin A storage after about 9 mo. on the ration, and most of the lambs born were weak and died soon after birth. In the final trial when ewes were depleted of vitamin A to the point of night blindness at breeding time about 65 percent of the ewes conceived, but gestation was unsuccessful and all the lambs were born dead or died within 24 hr. Ewes on a low protein, low phosphorus diet were more severely affected and produced a markedly lower percentage lamb crop than ewes on a low protein intake alone, although the low phosphorus ration supplemented with cod-liver oil did not lead to depletion of the blood phosphorus.

The influence of quantity of feed on the growth and properties of wool, J. C. SWABR (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 36 (1936), No. 2, pp. 197-226, figs. 57; *Ger. abs.*, pp. 224-226).—In this study conducted at the University of Stellenbosch, Union of South Africa, two groups of six Merino wethers each were employed. A typical hay-grain ration was fed, one group at a level considerably above maintenance and the other at a slightly submaintenance level. A study of the relationship between live weight gains and average total weight of grease wool, average staple length, average number of crimps per inch, and average diameter of fibers led to the following conclusions: (1) Increased feed consumption as indicated by increased body weight results in an increase in fleece weight; (2) Merino sheep on a submaintenance ration will grow wool at the expense of body maintenance; (3) increase in body weight is accompanied by an increase in staple length (coefficient of correlation= 0.717 ± 0.147), back wool being more sensitive to an increased ration and less sensitive to a decreased ration than britch wool; (4) increase in body weight is negatively correlated to the number of crimps per inch of fiber from shoulder, back, and britch samples (coefficient of correlation= -0.723 ± 0.144); and (5) increase in body weight is accompanied by an increase in average diameter of fibers (coefficient of correlation= 0.604 ± 0.192). Fiber diameters for a given body area vary less on the lower plane of feeding. The order of variability in fiber thickness ranging from greatest to smallest usually is britch, back, belly, and shoulder.

Peanut hay as feed for sheep, C. T. VAN RENSBURG (*Farming in So. Africa*, 12 (1937), No. 134, pp. 197, 202, figs. 4).—Brief trials comparing the feeding value of peanut hay and cowpea hay for ewes and lambs are reported. The peanut hay proved palatable, and the live weight gains of both ewes and lambs receiving it slightly exceeded the gains in the cowpea hay-fed groups.

The wintering of ewe hoggs, A. H. H. FRASER (*Scot. Jour. Agr.*, 20 (1937), No. 2, pp. 166-172).—Comparative trials in wintering ewe lambs on the native hill pastures and in the lowlands indicated that, because of the high percentage mortality and the risk of permanent stunting and development of undesirable conformation, wintering the lambs on the hill pastures was unsatisfactory. Experiments in feeding mineral supplements and protein and carbohydrate feeds in economic quantities showed that these practices were not a satisfactory substitute for wintering in the lowlands.

Producing native lambs: Rations for ewes suckling lambs, 1930-1931-1932, C. HARPER (*Indiana Sta. Bul.* 419 (1937), pp. 15).—The experiment reported has as its object a comparison of the relative values of various rations in producing milk from ewes as measured by the gains and finish of the lambs while they were suckling their mothers. Four lots of approximately 20 grade western ewes each were employed in each of the three seasons. The rations fed the ewes in lot 1 were whole oats and early-cut

timothy hay; lot 2, whole oats and good quality clover hay; lot 3, shelled corn and good quality clover hay; and lot 4, whole oats, cottonseed meal, and good quality clover hay. The lambs were all sired by purebred Shropshire rams, and all were fed exactly alike, receiving shelled corn and clover hay in creeps in addition to milk received from their mothers.

Good quality clover hay proved more efficient than the early-cut timothy hay in the ewe ration. The lambs made slightly greater average daily gains and the ewes lost less weight during the suckling period and produced somewhat more wool. There was little difference between shelled corn and oats as a grain feed for ewes. There was no essential difference in average gain of the lambs or in loss of weight of the ewes, and only a slightly greater wool clip in favor of the oats ration. The addition of cottonseed meal to a ration of oats and clover hay improved its value, resulting in greater gains and better finish of the lambs and decreased weight losses of the ewes, with no essential difference in wool clip from the two lots. It is suggested that, because of the small differences in favor of the supplemental ration, the quality of the grain and roughage available should have a bearing on whether to feed a protein supplement in the winter ration of ewes.

Effect of acid silage on the metabolism of sheep and pigs, with special reference to sulfuric acid as an acidifying agent [trans. title], W. KIRSCH and F. GRAMATZKI (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 36 (1936), No. 1, pp. 101-107).—Digestion and balance trials with a wether receiving grass and clover silage plus 0.5 percent of sugar over a 9-day experimental period and on a similar silage ration in which the sugar was replaced by 10 equivalents of sulfuric acid per 100 kg of silage plus 5 g of calcium carbonate daily over a second 9-day period indicated that the digestibility and starch equivalents of the two rations were similar, and that the substitution of acid for sugar had only a slight effect on the nitrogen, calcium, and phosphorus balances. Similar trials with a boar indicated that 0.5 percent of sugar in a basal ration of potatoes, crushed barley, and fish and meat meal could be replaced with a mixture of hydrochloric and sulfuric acid either with or without additions of calcium phosphate without altering the nutritive value of the ration.

Recent advances in pig breeding and fattening in Sweden [trans. title], N. PETERSEN (*Ztschr. Schweinezücht.*, 43 (1936), No. 36, pp. 571-573).—The methods employed and the results obtained at the Swedish pig-litter testing stations are summarized. In comparing the Swedish Landrace and Large White Yorkshire breeds the Landrace showed more rapid growth and lower feed consumption, but the Large White showed smaller loss at slaughter and also a higher percentage of high-grade pigs with thinner back fat, thicker belly, and somewhat greater body length.

Different methods of pig fattening in Sweden [trans. title], N. PETERSEN (*Ztschr. Schweinezücht.*, 43 (1936), No. 40, pp. 632-636, figs. 3).—This article presents pig-feeding standards as adopted in Sweden and also reports the results of pig-feeding experiments in which four groups of pigs were fed at the following levels during the growth and fattening periods: (1) Standard throughout, (2) standard up to 50 kg of live weight and full-fed thereafter, (3) full-fed throughout, and (4) standard up to 50 kg of live weight and 10 percent reduction thereafter. The average daily gains were 0.613, 0.623, 0.637, and 0.592 kg and the feed units per kilogram of gain were 3.82, 3.92, 4.04, and 3.74 for the respective lots. Slaughter losses were practically identical for all groups (from 25.3 to 25.7 percent).

The use of wood sugar in pig fattening [trans. title]. STAHL (*Ztschr. Schweinezucht*, 43 (1936), No. 30, pp. 471-473).—Wood sugar, prepared by the action of acid on wood, distilling off the liquid, and neutralizing with chalk, was shown to have a rather high feeding value in digestion trials with pigs and wethers. Replacing one-sixth of the barley with the sugar in a barley-fish meal ration for pigs did not decrease the value of the ration, and one-third of the potato flakes could be replaced by wood sugar when pigs received potatoes ad libitum in addition to a basal barley-fish meal ration. Pigs on the wood sugar rations yielded firm carcasses of good color.

Chronic zinc-poisoning of pigs: Results of experimental feeding of pure zinc lactate, R. E. R. GRIMMETT, I. G. McINTOSH, E. M. WALL, and C. S. M. HOPKIRK (*New Zeal. Jour. Agr.*, 54 (1937), No. 4, pp. 216-223, figs. 3).—On feeding for 2 mo. approximately 0.1 percent of zinc as zinc lactate in the milk with a small amount of meal, three young weanling pigs showed a stiffness in action, a roughness of coat, and a reduced feed intake. A few days later they became quite lame. Analysis of the blood at this time revealed a normal calcium and phosphorus content. All pigs were slaughtered soon after lameness occurred. Post-mortem examination revealed an apparently normal alimentary tract. Damage to the liver was observed in one case and some damage to the kidneys in all cases. Examination of the long bones showed that the humerus was badly damaged in each instance, the cartilage having lifted off a spongy underlying bone, with some erosion and considerable fluid in the humeroradial joints. This nonspecific arthritis apparently was produced by an upset of mineral metabolism resulting from prolonged zinc feeding.

Carcass-quality in bacon pigs, I, II, C. P. McMEEKAN (*New Zeal. Jour. Agr.*, 54 (1937), Nos. 3, pp. 147-158, figs. 5; 4, pp. 223-231, figs. 3).—Two studies are reported by the Massey Agricultural College.

I. *New Zealand bacon pigs in relation to United Kingdom market requirements.*—Study revealed that shortness in length of loin and a tendency toward overfatness were the most serious weaknesses. A comparison of carcass quality score for Large White, Tamworth, and Large Black purebreds, and Tamworth × Berkshire, Tamworth × Large White, Tamworth × Large Black, and Large White × Berkshire cross-breds showed that, while there was little difference in carcass quality score as a whole for the different lots, they did vary significantly in efficiency with respect to individual quality points. These differences within each breed and cross-bred lot indicated the possibilities of developing suitable bacon strains through selection.

II. *The influence of supplementary concentrates on carcass-quality.*—Feeding tests were conducted with approximately 100 pigs divided into groups, each lot receiving factory buttermilk ad libitum, while supplementary grain feeding ranged from none to 2 lb. per 100 lb. of live weight daily. There was no evidence that buttermilk alone produced abnormally thin bellies or that the addition of meal increased the thickness of belly. Additions of meal to the buttermilk ration increased the proportion of fat in the carcass, although this difference was not marked when grain feeding did not exceed 1 lb. per 100 lb. of live weight daily. The fat of all pigs on such rations was particularly hard. The type of pigs had a greater influence than the type of diet on the proportion of fat to lean in the bacon carcass.

Pork production, W. W. SMITH (*New York: Macmillan Co.*, 1937, rev. ed., pp. XXII+575, figs. 88).—This revised edition (E. S. R., 44, p. 571) has summarized the available results of experimental studies, but has retained the original outline of subject matter and plan of presentation.

The influence of salt on the nitrogen balance of hens, J. S. WILLCOX (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 2, pp. 121-134, figs. 5; Ger. abs., p. 134*).—In a nitrogen balance experiment conducted at the University of Leeds with four Rhode Island Red hens, a well-balanced basal ration containing no salt was compared with the same ration plus 1 percent of salt. Variations in nitrogen consumption and retention from day to day apparently were not conditioned either by egg laying or by loss of nitrogen in feathers due to molting. The addition of 1 percent of salt to the ration exerted a favorable effect on total feed and nitrogen consumption, but there was no conclusive evidence that its presence enhanced the nitrogen retention.

Methods and rations for fattening poultry, H. S. GUTTERIDGE (*Sci. Agr., 17 (1937), No. 6, pp. 340-358; Fr. abs., p. 358*).—This study conducted at the Central Experimental Farm, Ottawa, consisted of two major phases, first, the conducting of actual fattening trials with poultry and, second, the consideration of criteria suitable for judging the ability of a feed to fatten. Two 21-day fattening trials are reported, one with White Leghorn capons and the other with Barred Plymouth Rock cockerels, involving in all 10 feeding trials and one matter of feeding technic. The method of allotting birds to the various groups, the actual technic of feeding and management, the sampling of tissues for chemical analyses, the chemical analyses, and the biometrical treatment of the data are each fully discussed.

It is concluded that (1) the feeding of a fattening mash in dry form with skim milk to drink and both before the birds constantly gave inferior weight gains as compared with feeding the same mash moistened with twice its weight of skim milk and fed twice daily for 30-min. periods; (2) pen feeding was less efficient than crate feeding; (3) potatoes whether raw or cooked were unsatisfactory as a supplement to the wet mash ration; (4) ground yellow corn with skim milk was much more efficient than ground wheat with skim milk or a mixture of 2 parts of ground oats and 1 part of ground barley with skim milk; (5) 10 percent of meat meal proved a valuable supplement to a mixture of 2 parts of oats and 1 part of barley; and (6) 15-min. feeding periods proved as efficient as 30-min. periods.

Weight gains in dressed poultry did not seem to be a satisfactory indication of the efficiency of a feed or treatment to increase fat. The percentage of fat in tissues at the end of a fattening period may be a poor criterion of fat increase during an experiment because of undetermined variations in degree of fatness of different breeds at the beginning of a trial. The distribution of body fat is unimportant as a criterion for the fattening efficiency of a feed. Methods are suggested for adjusting weight gains to compensate for variations in initial weight and in feed consumption.

The effect of certain calcium intake levels on hatchability and egg shell formation (*Rhode Island Sta. Rpt. [1936], pp. 38, 39*).—When mash rations containing 1.99, 2.93, and 5.2 percent calcium without oystershell and 1.46 percent calcium plus oystershell ad libitum were fed to laying hens the average calcium content of the eggshells was 1.57, 1.69, 1.79, and 1.96 g, respectively.

The hatchability of chicken eggs as influenced by environment and heredity, W. LANDAUER [*Connecticut Storrs Sta. Bul. 216 (1937), pp. 84, figs. 21*].—This is a comprehensive summary based on a critical examination of the whole field and presents not only the results of investigations at the station but also a general review, including a great deal of data from other sources. In successive sections of the bulletin are discussed the physical environment of hatching eggs, the chemical environment during incubation, egg traits which influence hatchability, nutrition, age and reproductive activity of parent

stock and metabolism of laying hens as factors in hatchability, genetic factors affecting hatchability, and embryonic development and hatchability. An extensive bibliography is appended.

Meat scraps and dried milk in rations for starting chicks, R. E. ROBERTS and C. W. CARRICK (*Indiana Sta. Bul. 421 (1937), pp. 27, fig. 1*).—The results of four series of experiments are reported. In all cases either Barred Plymouth Rock or Single Comb White Leghorn chicks were used. They were placed in experimental pens at from 24 to 48 hr. of age, and in most cases the trials extended over a 10-week period. The mixed rations were fed as a dry mash and kept before the chicks at all times, and water was provided ad libitum.

In the first experiments, designed to determine the optimum amounts of protein supplements to be used in the rations, it was found that 15 percent of meat-and-bone scrap and 5 or 6 percent of dried milk produced more rapid growth and the amount of feed required per unit of gain was less than when 12 percent of meat-and-bone scrap and 4 percent of dried milk were fed. The higher rate of gain was, however, approximately offset by the increased cost of the ration. No differences in mortality could be attributed to the type of ration.

In a study of the optimum proportion of meat-and-bone scrap and dried milk in the ration, ratios of 3:1, 1:1, and 1:3 were maintained. At these levels no differences in rate of gain, mortality, or feed required per unit of gain were observed, and males and females were equally efficient in converting feed into gain.

A comparison of dried buttermilk and dried skim milk as supplements to the starting ration indicated little difference in their relative feeding value. A slight advantage in favor of dried buttermilk was of doubtful significance.

A comparison of dried milk and dried whey as supplements indicated that the dried milk was superior when the two were fed in equal amounts, but when fed at such levels as to provide equal amounts of protein they produced practically the same rate of growth. There was no difference in mortality or in feed required per unit of gain on the two rations.

The utilization of food elements by growing chicks.—I, A comparison of protein concentrates from animal and vegetable sources, C. W. ACKERSON, M. J. BLISH, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul. 90 (1937), pp. 8*).—Two lots of 15 newly hatched White Rock chicks each were used in this study, the paired feeding technic being employed. A basal mixture made up 85 percent of each ration and mixtures of dried buttermilk, fish meal, meat scraps, and cornstarch 4.5:4.5:4.5:1.5 and soybean meal, corn gluten meal, wheat gluten meal, and tricalcium phosphate 7.5:3.38:3.38:0.75, respectively, comprised the remaining 15 percent of the rations. The two rations were very similar in chemical composition. The results were measured in terms of growth over a 60-day feeding period and comparative slaughter tests involving the determination of nitrogen, calcium, and phosphorus in the bodies of the chicks. The percentage rate of gain and the gain per gram of nitrogen fed were greater in the lot fed the animal protein concentrate. There was no difference between the lots with respect to calcium and phosphorus contents in the chick bodies, but the nitrogen content of the group receiving animal protein was somewhat greater. Nitrogen retention was somewhat higher on the animal protein diet, but calcium and phosphorus retention was lower than on the vegetable protein diet.

Differentiation between vitamin B₁₂ deficiency and "encephalomalacia" in growing chicks, C. A. ELVEHJEM, P. H. PHILLIPS, and E. B. HART (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 2, pp. 129-131, figs. 2).—In a previous report (*El. S. R.*, 71, p. 364) it was stated that a form of chick paralysis re-

sulting from vitamin B₁₂ deficiency in the ration was probably the same as that described by Pappenheimer and Goettsch.² This article describes and illustrates the type of chick paralysis due to vitamin B₁₂ deficiency (E. S. R., 76, p. 515) and also describes an encephalomalacia-like paralysis produced at the Wisconsin Experiment Station. The two forms are clearly differentiated, and the latter type appears to be very similar to that described by Pappenheimer and Goettsch.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in Idaho], D. R. THEOPHILUS (*Idaho Sta. Bul.* 221 (1937), pp. 27–30, fig. 1).—Results of dairy cattle studies are noted on the effect of the continuous use of sires proved for high production and acceptable type, pea germ meal as a source of vitamin E, the solids-not-fat content of milk as a heritable factor, and the reliability of selected tests for detecting mastitis.

Dairy products studies gave information on the relation of bacteria and enzymes to the development of wintery flavor in butter, and the effects of feeding alfalfa hay on the Reichert-Meissl and iodine values of butterfat.

[Investigations with dairy cattle and dairy products] (*Massachusetts Sta. Bul.* 339 (1937), pp. 18–21, 23, 42, 44).—Results are briefly noted on the effect of feeding a vitamin A concentrate on reproduction in cattle, by J. G. Archibald, V. A. Rice, and O. H. Parsons; the chemistry of pasture grass, by Archibald; and performance prediction from pedigrees, by Rice.

Dairy products studies reported include the influence of added iodine on the properties and bacterial flora of milk, by J. E. Fuller and G. S. Congdon; the effect of aging treatments on the Tyndall phenomenon of gelatin-water solutions, by W. S. Mueller; and the efficiency of water heaters, electric sterilizers, and electrically operated cooling tanks, by J. H. Frandsen, H. G. Lindquist, and M. Glickstein.

The influence of normal and extracted soybeans on milk production and quality of butter [trans. title], V. HORN and E. MÜHL (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 9 (1937), No. 1, pp. 1–31; *Eng. abs.*, p. 31).—In a series of trials with milking cows whole soybeans in a ration proved to be very palatable. When 35 percent of the concentrate check ration was replaced by soybeans an increase of 53 percent in milk yield and 5.6 percent in fat yield occurred, while little effect on the percentage of fat in the milk was noted. At this level of feeding the quality of the milk was not impaired but the quality of the butter was injured, resulting in a pronounced soybean flavor and soft body. The addition of 30 percent of palm kernel cake to the ration markedly increased the firmness of the butter. When 35 percent of extracted ground soybeans were included in the concentrate ration an increase of 4 percent in milk yield and 3.8 percent in fat yield occurred. The average percentage of fat in the milk was not changed. The butter had a desirable flavor and aroma, and the body was firm and hard without additions of palm kernel cake or feeds of a similar nature.

The influence of feeding untreated and disemibittered vetch seed to cows on the yield and fat content of milk [trans. title], K. RICHTER and J. HERBST (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 9 (1937), No. 1, pp. 32–38; *Eng. abs.*, p. 38).—Vetch seed (*Vicia sativa*), disemibittered by steaming for 10 min. at from 95° to 105° C., was compared with untreated vetch seed in a double reversal feeding trial with nine milking cows when fed at the rate of 3 kg of

² Jour. Expt. Med., 53 (1931), No. 1, pp. 11–26, pls. 3, figs. 2.

air-dried seed per day. There were no significant differences in the milk yield or butterfat content of the milk produced.

The influence of feeding untreated and disembittered vetch seed on the composition and quality of milk, butter, and whipped cream [trans. title], F. RICHTER (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 1, pp. 39-51, figs. 2; Eng. abs., p. 51*).—A further study of the milk produced during the above-described feeding trial indicated that the composition and reaction of the milk was unaltered when the animals were changed from one type of ration to the other. Milk produced on the untreated vetch seed ration was better adapted for cheese making. When the animals were first fed the untreated seed the milk had a pronounced disagreeable odor and flavor. This condition persisted to some extent when the animals were changed over to the disembittered seed ration, but gradually disappeared and did not increase in intensity when they were again fed untreated seed. Butter flavors were adversely affected only during the first period on untreated seed. Butter produced on the untreated seed ration had a high degree of hardness but was somewhat softer when disembittered seed was fed. No specific differences in quality of whipped cream could be determined.

Feeding trials with vetch seed for milking cows [trans. title], H. BÜNGER, J. SCHULTZ, and H. AUGUSTIN (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 2, pp. 106-114; Eng. abs., p. 114*).—Either untreated vetch seed or steamed vetch seed were used to replace a mixture of palm kernel cake and extracted ground soybeans in double reversal feeding trials with milking cows. The steamed seed proved somewhat more palatable than the untreated seed, but neither were observed to exert any deleterious effect on the animals. The untreated seed maintained approximately the same average milk production as the check ration, while production was slightly decreased with the steamed seed. It is concluded that up to 1.5 kg (3.3 lb.) of untreated vetch seed per cow daily can be safely fed.

Studies of vetch seed, with reference to the presence of toxic substances [trans. title], G. SCHWABZ and H. FINZENHAGEN (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 2, pp. 115-120; Eng. abs., p. 120*).—The presence of saponins could not be positively identified either in untreated or steamed vetch seed, but the untreated seed was found to contain about 0.05 g of prussic acid per 1,000 g of air-dried seed. Subjecting the seed to soaking and then steaming resulted in the removal of most of the prussic acid, and it is believed that by sufficient soaking and steaming it would be possible to extract it completely.

Feeding dairy calves with very limited quantities of whole milk [trans. title], L. PALOHEIMO (*Biedermanns Zentbl., Abt. B, Tierernähr., 9 (1937), No. 1, pp. 52-73, fig. 1; Eng. abs., pp. 72, 73*).—Trials were reported in which 190 Ayrshire calves were successfully raised to ages ranging from 90 to 120 days on very limited whole milk rations. The total quantity of whole milk fed was under 20 kg (44 lb.) in most cases. Other ingredients of the ration included limited amounts of skim milk, hay, either corn meal or ground oats, and small supplements of cod-liver oil. Live weight gains compared favorably with the "Eckles normal" for Ayrshire calves, and acute digestive disturbances were encountered in only two cases. Corn was considered a better concentrate than oats for young calves. Twenty-two calves raised by this method were maintained in the breeding herd and developed into cows of normal size and good producing ability.

Records, cows, and indexes, J. L. LUSH (*Holstein-Friesian World, 34 (1937), No. 11, pp. 11, 12, 28*).—The Iowa Experiment Station has studied the

relationship between the first milk production records of cows and later records by the same individuals, i. e., the repeatability of records from one year to another. It was found that on the average differences between single records made in the same herds in Iowa Cow-Testing Associations are caused about 40 percent by permanent differences between abilities of the cows which made the records and 60 percent by environmental factors which vary from one lactation to the next for the same cow. The application of these findings to the computation of sires indexes is discussed.

Observations on the source of flavor in milk exposed for prolonged periods to radiation. K. G. WICKEL and H. C. JACKSON (*Food Res.*, 1 (1936), No. 5, pp. 419-426, fig. 1).—The Wisconsin Experiment Station has ascertained the relationship existing between the constituents of milk and the development of activated flavor, using the same sources of radiant energy as previously noted (E. S. R., 77, p. 238). Three procedures were followed: First, the irradiation of fluid dairy products of different composition; second, the irradiation of constituents and fractions separated from milk; and, third, the separation of constituents and fractions from milk which had been previously irradiated.

The results indicate that the activated flavor resulting from irradiation is distinctly different from the commonly described oxidized flavor and that activated flavor originates in or is closely associated with the protein fraction of the milk. However, activated flavor may be present in the fat, probably due to absorption of such flavors by the fat. Albumin developed a more intense activated flavor than casein. The presence of activated flavor in the filtrates after the removal of casein and albumin was attributed to the effect of radiation on the soluble minor proteins and to absorption from the casein and albumin. Prolonged irradiation produced an altered flavor in milk exposed to the radiation transmitted through glass as well as through quartz, whereas milk constituents acquired an altered flavor when individually subjected to radiation transmitted through quartz, but not when the radiation was transmitted through glass.

The effect of fat content on oxidized flavor in milk and cream. C. T. ROLAND and H. A. TREBLER (*Jour. Dairy Sci.*, 20 (1937), No. 6, pp. 345-350, fig. 1).—Four experiments are reported in each of which a series of products was prepared by combining skim milk and cream (separated at 95° F.) from the stock milk in different proportions to give a range in fat content. Coils of copper wire of given surface areas were immersed in 100-cc lots of each product. The samples were then pasteurized, bottled, cooled, stored at 40°, and sampled after 24 and 48 hr. in storage.

The sensitivity of the standardized milks and creams to copper-induced oxidized flavor was shown to be definitely related to the fat content of the product, susceptibility increasing with increased fat content. A variation of 1 percent fat in the range of whole milk resulted in significant differences in flavor score. Skim milk samples exposed to large areas of copper failed to develop oxidized flavor. Milks made by recombining skim milk and cream were markedly less sensitive to copper-induced oxidized flavor than normal whole milk of like fat content. Bacterial examination of the samples showed no appreciable growth of micro-organisms during the experiment, indicating that bacterial activity was not a factor in decreased sensitivity. The removal of lecithin or related substances by the separator or changes in their distribution between the fat and aqueous phases are suggested as the cause for the decreased sensitivity.

Homogenization as a preventive of oxidized flavor. H. E. ROSS (*Milk Plant Mo.*, 26 (1937), Nos. 4, pp. 36-39; 5, pp. 40-42, 44).—This article from

the [New York] Cornell Experiment Station describes a series of experiments in which samples of whole milk and cream were subjected to homogenization at various pressures. In practically all cases the untreated control samples failed to develop oxidized flavor during the period of 96 hr. Running samples through the homogenizer at 0 pressure usually resulted in the development of a pronounced oxidized flavor. Homogenizing at 500 and 1,000 lb. pressure per square inch was partially effective in preventing the development of oxidized flavor but such treatments could not be recommended as satisfactory, whereas 1,500 lb. pressure proved very effective in preventing such flavors in either milk or cream. Efforts to produce oxidized flavor by soaking copper strips in unprocessed milk or cream and by adding various concentrations of copper sulfate to such samples invariably resulted in intense oxidized flavor. Similar treatment for milk and cream samples homogenized at 1,500 lb., with two exceptions, were protected against development of such flavors. Homogenization was wholly ineffective in destroying or reducing oxidized flavors once they had developed. The hypothesis is advanced that the prevention of oxidized flavor by homogenization may be due to the formation of a film around the fat globule.

Iodine in the milk (*Kentucky Sta. Rpt. 1936, pt. 1, p. 23*).—Trials in cooperation with Berea College are reported on the effect of adding kelp to the dairy ration.

Bacterial content of milk as affected by the use of different plating methods, A. BRADFELD (*Vermont Sta. Bul. 417 (1937), pp. 54*).—The tryptone-glucose-skim milk agar formulated by Bowers and Hucker (*E. S. R., 73, p. 837*) was compared with standard agar both at incubation temperatures of 32° and 37° C., using normal types of both raw and pasteurized milks as well as milks heavily contaminated from specific sources. The modified medium gave higher average counts than the standard, and both gave markedly higher counts at 32° than at 37°, with greater increases resulting from the lowered incubation temperature than from change of medium. The modified medium at 32° gave a much higher percentage increase in count for pasteurized milk than for raw milk. Organisms derived from udders, feces, hair, or bedding grew practically as well on the standard as on the modified medium, while those derived from unsterile utensils, feed, and stable dust or those developing because of inadequate cooling grew in greater numbers on the modified medium and at the lower temperature. On the whole, the modified medium at 32° proved to be more accurate and consistent than the present standard method for estimating the numbers of bacteria in milk. A good quality milk will not be seriously penalized if this modified method is employed. Skim milk is considered an important constituent of these media, and readily soluble dry milk solids added with the other ingredients appear as effective as skim milk.

A partial report of this work was previously noted (*E. S. R., 76, p. 385*).

A statistical comparison of two methods for determining the bacterial count of milk, J. M. FRAYER (*Vermont Sta. Bul. 423 (1937), pp. 19, figs. 3*).—In this study the bacterial counts of 18 samples of milk as determined by the standard agar plate method and by use of the Bowers-Hucker medium (*E. S. R., 73, p. 837*) incubated at 32° C. for 48 hr. were compared. From 20 to 100 replicate plates were prepared from each sample, and each plate was counted from 3 to 6 times and by 3 different technicians, involving 4,709 counts in all. These data were then analyzed by simple statistical methods to show something of the relative value of each method for the purpose intended. It is concluded that the modified method produced a greater number of more luxuriant colonies. The modified medium because of its inherent opaqueness in-

creased the visibility, especially of the smaller colonies, so that counting accuracy was augmented. On the whole, it appeared significantly better adapted to the purpose than the present standard method.

Dyes and methods as they affect the methylene blue test, J. M. FRAYER (*Vermont Sta. Bul.* 424 (1937), pp. 16).—Three methods of conducting the methylene blue reduction test were compared, 50 to 100 replicate tests being made on each milk sample and involving in all 4,347 tests. In the first method the tubes were stoppered and protected from light and were not touched after being placed in the water bath until reduction was complete. In the second method the tubes were similarly handled but were carefully inverted once after 5 minutes' immersion in the water bath. In the third method the tubes were carefully inverted (not shaken) at 30-min. intervals in order to keep the fat and micro-organisms in more or less homogeneous dispersion. A statistical analysis of the data resulting from these methods indicated that the third method gave shorter and significantly more reliable reduction time than the other two, due primarily to more uniform bacterial dispersion brought about by the frequent inversion. A comparison of methylene blue thiocyanate and methylene blue chloride indicated that when used in approximately equal concentrations reduction times were very similar. Significantly longer reduction times elapsed when either dye was used in a concentration of 1:300,000 than when used at a concentration of 1:700,000.

Significance of the hemolytic streptococci found in milk, J. H. BROWN (*Cornell Vet.*, 27 (1937), No. 2, pp. 110-121, figs. 5).—This report indicates that in the routine examination of milk for the presence of β -hemolytic streptococci likely to produce disease in man or mastitis in cattle, the simple procedure of inoculating sorbitol broth and hippurate broth with hemolytic colonies from blood agar plates will give a satisfactory test in over 99 percent of the cases. Strains which are both sorbitol-negative and hippurate-negative, i. e., that fail to ferment sorbitol or to hydrolyze the hippurate, are the types highly pathogenic to man. The sorbitol-negative hippurate-positive strains are the ones commonly causing mastitis in cows but are not pathogenic to man, and the sorbitol-positive hippurate-negative strains apparently nonpathogenic to man may cause mastitis. The sorbitol-positive hippurate-positive strains are considered nonpathogenic to man and are of doubtful significance in milk.

The genera *Sporobolomyces* and *Bullera* from the standpoint of dairy products, H. C. OLSON and B. W. HAMMER (*Iowa State Col. Jour. Sci.*, 11 (1937), No. 2, pp. 207-213, pl. 1).—Studies of the numbers of micro-organisms falling from the air in dairy plants (El. S. R., 72, p. 683) yielded certain organisms which discharged spores from colonies in such manner that when plates were inverted definite spots occurred on the covers directly beneath the colonies. By inverting acidulated malt agar or potato dextrose agar plates which had been exposed to the air over sterile malt agar plates a total of 32 cultures were isolated and studied. Twenty-six were identified as belonging to the genus *Sporobolomyces* and six to the genus *Bullera*, also one *Sporobolomyces* was isolated from fermented cream. The cultures included *S. salmonicolor*, *S. roseus*, a new species for which the name *S. pararoseus* is suggested, and *B. alba*. *S. pararoseus* is fully described, and the description of *B. alba* is extended. It is concluded that *Sporobolomyces* and *Bullera* organisms are unimportant in dairy products, either from the standpoint of the numbers present or the production of defects.

Why sweet cream is thick or thin, J. C. HENING (*Farm Res. [New York State Sta.]*, 3 (1937), No. 4, p. 7).—This note briefly discusses the effect of the

percentage of butterfat, temperature, aging, and pasteurization on the thickness of sweet cream.

Age and fat per cent: The relation of butter fat percentage of the first lactation to that of subsequent lactations, C. W. TURNER (*Guernsey Breeders' Jour.*, 51 (1937), No. 10, pp. 924, 925).—This study at the Missouri Experiment Station compared the butterfat percentage of the re-entry records of the Advanced Register Guernsey cattle with the butterfat percentage of the original entry record, a total of 5,847 pairs of 365-day records being included. The average test of the original entry record was 5.084 and of the re-entry records 5.066. The coefficient of correlation between entry and re-entry records was $+0.847 \pm 0.0527$. Over 80 percent of the pairs of fat percentages did not vary more than 0.5 percent, indicating that the change in fat content with age is very slight.

Churn loss factors and neutralization of cream, E. W. BIRD (*Amer. Creamery and Poultry Prod. Rev.*, 83 (1937), No. 19, pp. 698, 699).—In discussing butterfat losses in churning it is indicated that greater fat losses occur in low testing cream than in higher testing cream, and the following formula,

$$\text{pounds of fat lost per 100 lb. churned} = \frac{(100 - 1.2 \times \text{cream test}) \times \text{buttermilk test}}{\text{cream test}}$$

is proposed for estimating churn losses of fat. Studies with cream which was pasteurized while sweet and then ripened indicated little change in fat losses for cream of a given fat content as the acidity increases within a pH range of 7.0 to 4.5. However, when sour cream is pasteurized and then neutralized the minimum fat losses occur at a pH of 6.75 to 7.0, with increases in fat loss as the pH varies in either direction. With regard to cream neutralization information is presented on the approximate pH resulting when various neutralizers are used to obtain a titratable acidity in cream of 0.25 percent. A close agreement was noted between the pH values of cream and of the resulting butter, with a tendency for the pH of the butter to be slightly higher than the cream. Butter scores were higher and tended to maintain themselves better in the pH range of 6.8 to 7.4 than at lower acidities.

A holding test at room temperature as an indication of the keeping quality of butter in storage, D. H. JACOBSEN (*South Dakota Sta. Bul.* 308 (1937), pp. 35, figs. 2).—In this study of the efficiency of a short-time holding test for predicting the keeping quality of butter in storage both unsalted and salted samples of each lot were tested.

When unsalted butter and butter serum therefrom were held at 21° more rapid and extensive flavor deterioration and more rapid increase in numbers of bacteria occurred in the serum than in the corresponding butter, but the serum was of little value in predicting keeping quality of the butter since the flavor defects were frequently quite different from those produced in the butter. Salted butter held for 7–10 days at 21° did not show flavor deterioration except for tallowiness, hence such a test gave no information for predicting the keeping quality of salted butter. Salt in butter (2.5 percent) effectively prevented the growth of lipolytic and proteolytic bacteria in both the butter and serum under the holding conditions of this experiment. Holding samples of unsalted butter for 7–10 days at 21° gave useful information on the keeping quality of such butter at lower temperatures. Bacterial counts of similar magnitude were reached after 2, 7, 21, and 56 days at 21°, 15°, 5°, and 0°, respectively. However, growth of bacteria at 21° was apparently not as much of a factor in flavor deterioration as the growth of similar numbers at lower temperatures because of the more extensive development of lipolytic

and proteolytic types at the lower temperatures. Flavor deterioration within 7-10 days at 21° invariably indicated flavor deterioration within 56 days at either 5° or 0°, but failure to show flavor defects at the higher temperature did not always insure good keeping quality at the lower temperature. The increase in the numbers of bacteria and flavor defects in unsalted, noncultured butter was much more extensive than in unsalted, cultured butter at similar temperatures. Rancidity and cheesy flavor in unsalted butter at 5° or 0° were frequently accompanied by large numbers of lipolytic and proteolytic bacteria, respectively, and both defects often occurred in the same sample.

A study of sugaring curds in the manufacture of Cheddar cheese, J. C. MARQUARDT (*Natl. Butter and Cheese Jour.*, 28 (1937), No. 10, p. 14).—Trials at the New York State Experiment Station in which 0.75 percent of cane sugar was added to milled Cheddar cheesecurd just prior to salting indicated a consistent reduction in moisture content and improvement in body and flavor of the ripened cheese as compared with control lots from the same vats which did not receive sugar. The milk used in various trials ranged in quality from the types commonly used in cheese making to that suitable for fluid milk purposes. It is suggested that sugaring curds in making Cheddar cheese could well be introduced as a standard because of the moisture reduction and quality improvement.

Results of treating cheese milk or fresh curds with cured cheese, J. C. MARQUARDT (*Natl. Butter and Cheese Jour.*, 28 (1937), No. 11, pp. 20, 22).—Trials were conducted at the New York State Experiment Station in which 1 percent of Limburger, 1 percent of Roquefort, or 0.25 percent of Sapsago cured cheese was added to cheese milk. In other trials 5 percent of Limburger, 5 percent of Roquefort, or 2.5 percent of Sapsago cheese was added to the freshly matted Cheddar curds. All cheeses were scored for body and flavor after 6-, 12-, and 18-week curing periods.

Adding the cured cheese to the milk did not significantly affect the scoring of the cheese. Flavor changes introduced by adding the Limburger or Roquefort were slight, but the addition of Sapsago produced a very desirable flavor characteristically different from the usual Cheddar cheese flavor. Adding Limburger or Roquefort cheese to the matting curd decreased the body and flavor score, while additions of the Sapsago to the curd had little effect on the score as compared with the control lots. It is concluded that cured cheese should never be matted with fresh cheesecurds in an attempt to modify cheese flavors.

Methods for the manufacture of smoked type cheese, J. C. MARQUARDT (*Natl. Butter and Cheese Jour.*, 28 (1937), No. 9, p. 10).—Trials were conducted at the New York State Experiment Station in which varying amounts of liquid smoke (pyroligneous acid) were added to the cheese milk, to the whey after cutting, or to the curd of both Cheddar- and Provolone-type cheeses, and the effect on body and flavor of the resulting cheese was noted. Liquid smoke could not be satisfactorily added to the curds, but additions directly to the milk or to the whey were successful. Additions of 0.02 percent or less of the liquid smoke directly to the milk resulted in a desirable mild smoked flavor in Cheddar-type cheese. No more than 0.1 percent of liquid smoke could be used satisfactorily in the strong flavored cheeses. Additions of 0.01 percent of liquid smoke to processed cheese imparted a pleasant smoked flavor. The possibilities of commercial application of this process are indicated.

Observations on the salting of brick cheese, E. L. BYERS and W. V. PRICE (*Jour. Dairy Sci.*, 20 (1937), No. 6, pp. 307-318, figs. 2).—A brick cheese curd manufactured by a process previously noted (E. S. R., 74, p. 252) was used in

this study at the Wisconsin Experiment Station. Loaves of the cheese were subjected to various salting treatments, including dry salting (rubbing with dry salt once a day for 2 days) and brine salting (22-percent brine for 24, 48, and 72 hr. and 26-percent brine for 48 hr.). All cheeses were salted at 60° F. and cured for 2 weeks at 60° with 85 percent relative humidity, during which period the cheeses were rubbed and washed with a 2-percent salt solution every other day. Cheeses were paraffined at 14 days and placed in curing cellars at 40° temperature and 75 percent relative humidity. Acidity, moisture, and salt determinations were made at regular intervals, and all cheeses were graded.

Observations on the rate of salt penetration indicated that salt rapidly penetrated the outer layer, but about 8 weeks elapsed before the salt concentration was uniform throughout the cheese. As the salt content of any given portion of the cheese increased the moisture content decreased, the increased salt failing to account for the marked decreased moisture content. Cheeses subjected to 22-percent brine for 24, 48, and 72 hr. contained 38.9, 36.5, and 36.1 percent moisture and 1.9, 2.5, and 2.9 percent salt, respectively, at the end of 8 weeks' curing. Lots subjected to dry salting, 22-percent brine for 48 hr., and 26-percent brine for 48 hr. contained 36.1, 36, and 32.3 percent moisture and 1.4, 2.1, and 2.7 percent salt at the end of 8 weeks. It is concluded that long periods in the brine tank, highly concentrated brines, and early salting each increased the amount of salt in the cheese, and that dry salting was effective but less uniform than brine salting. Approximately 2-percent salt was considered an optimum content, excessive salting causing hard curdy body, white color, slow ripening, loss of yield, and delayed lactose fermentation, while low salt encouraged abnormal fermentation and caused weak body and open texture.

The influence of salt on the composition and quality of brick cheese, E. L. BYERS and W. V. PRICE (*Natl. Butter and Cheese Jour.*, 28 (1937), No. 14, pp. 10, 12, 14, 16).—This article presents essentially the same information as noted above.

Island of Orleans cheese, J. C. MARQUARDT (*Farm Res. [New York State Sta.]*, 3 (1937), No. 4, p. 8, figs. 2).—This article describes a type of cheese which is manufactured almost exclusively on the Island of Orleans near the city of Quebec, Canada. The cheese, known in French as Le Fromage Raffiné de l'Isle d'Orléans, or more commonly Fromage Raffiné, is a soft cheese having a strong characteristic flavor. It is made from fresh cows' milk and contains over 50 percent moisture and about 25 percent fat. Yeasts and molds enter into the curing process, and the cheese is quite perishable, hence its sale is largely confined to the Quebec market. Certain unusual practices involved in its manufacture are discussed.

The gas requirements of molds.—I, A preliminary report on the gas requirements of *Penicillium roqueforti* (various strains of blue mold from cheese), N. S. GOLDING (*Jour. Dairy Sci.*, 20 (1937), No. 6, pp. 319-343, figs. 6).—The Washington Experiment Station has studied the growth of various strains of *P. roqueforti* on different media and at incubation temperatures of 48°, 70°, and 85° F. as influenced by a high concentration of carbon dioxide or nitrogen in the surrounding atmosphere. The presence of carbon dioxide inhibited the growth of the several strains. The degree of inhibition was uniform with the medium, but varied with the concentration of carbon dioxide and the temperature. When the atmosphere was 75 percent carbon dioxide and 25 percent air, little more than germination occurred at 85°, the colonies attained about one-half normal size at 70°, and inhibition was almost total at 48°. Increasing the concentration of nitrogen in the atmosphere also affected the growth of the

several strains. In the presence of 3 parts of nitrogen to 1 part of air growth was slightly inhibited at 85°, normal at 70° and at 48° growth was considerably accelerated over that in air. At the latter temperature even in 9 parts of nitrogen to 1 part of air there was no inhibition. When cultures were subjected to an atmosphere of low oxygen pressure but from which all carbon dioxide was removed by sodium hydroxide as an absorbent, practically all the oxygen was removed by the growing cultures at both 70° and 48°, indicating that the presence of carbon dioxide and not the lack of oxygen was the inhibiting factor. The significance of these findings in relation to the selection of a satisfactory starter in the manufacture of blue-veined cheeses is discussed.

A flavor constituent of blue cheese (roquefort type), B. W. HAMMER and H. W. BRYANT (*Iowa State Col. Jour. Sci.*, 11 (1937), No. 3, pp. 281-285).—Experiments are reported in which the action of *Penicillium roqueforti* on various lower fatty acids was determined. Each of the fatty acids was added to sterile milk, and the milk was then inoculated with the mold spores and incubated at room temperature. In most cases a rapid development of mold occurred, and volatile acid determinations indicated that the fatty acids had largely disappeared. In the case of *n*-caprylic acid, no surface mold growth occurred for several days and an odor similar to the peppery odor of blue cheese was evident. Later mold growth developed and the characteristic odor disappeared. Other tests indicated that this odor was due to the formation of methyl-*n*-amyl ketone, and led to the conclusion that this product is formed from caprylic acid through the action of *P. roqueforti* under unfavorable growth conditions and that it is an important flavor contributant of blue cheese. This odor is conspicuous in many lots of cheese but is not evident in others, although it may be present to some extent and in the latter type of cheeses the desirable flavor appears to be supplied largely by the fatty acids.

The relationship between temperature and overrun in the whipping of ice cream mixes, A. LEIGHTON and A. LEVITON (*Jour. Dairy Sci.*, 20 (1937), No. 6, pp. 371-378, figs. 2).—Experiments conducted by the U. S. D. A. Bureau of Dairy Industry, in which ice cream mixes containing varying percentages of butterfat, serum solids, and gelatin and homogenized at different pressures were frozen at various temperatures, gave evidence that an equilibrium exists between temperature and the overrun attainable in freezing ice cream mixes. This relationship was expressed by the straight line equation:

$$\text{Percentage overrun} = At + B.$$

In this t is the temperature and A and B are constants for any given ice cream mix. This equation must be qualified by stating the maximum overrun attainable for the mix and also by a statement of the number of minutes the mix can be beaten in the freezer before instability results; also freezing the mix to too low a temperature causes a departure from this equilibrium. The relationship of these findings to the usual manufacturing procedure for ice cream is discussed.

Twenty-fourth annual report of the International Association of Dairy and Milk Inspectors, compiled by P. B. BROOKS (*Internat'l. Assoc. Dairy and Milk Insp. Ann. Rpt.*, 24 (1935), pp. 302, figs. 2).—The following papers are among those presented before the annual meeting held at Milwaukee, Wis., October 10-12, 1935 (E. S. R., 73, p. 840): The Coordination of American Milk Control Effort, by L. C. FRANK (pp. 9-21); Studies With A "Different Method" of Appraising Standard Plate Counts, by C. S. LEETE (pp. 28-39); Educational Work as a Factor in Increasing the Extent of Pasteurization, by I. V. HISCOCK (pp. 46-52); Radiation and the Microorganisms of Milk, by K. G. WECKEL (pp. 69-74); Progress in Standardizing Laboratory Procedures, by R. S. BREED

(pp. 109-114); The Value of the Colon Test as a Means of Detecting Unsanitary Conditions on the Farm, by M. W. Yale and R. Eglinton (pp. 116-125); Sources of Infection in Septic Sore Throat Epidemics, by G. H. Ramsey (pp. 163-169); The Numbers and Kinds of Bacteria in Aseptically Drawn Milk, by H. R. Thornton and N. J. Strynadka (pp. 173-188); A Study of the Nutritional Value of Raw and Pasteurized Milk, by C. A. Elvehjem (pp. 196-202); and Ice Cream Contamination by Dippers (in Retail Stores), by D. W. Horn (pp. 249-256).

VETERINARY MEDICINE

[Report of work in animal pathology and parasitology by the Idaho Station] (*Idaho Sta. Bul.* 221 (1937), pp. 23, 25, 26, 43-45, figs. 2).—The work of the year referred to (E. S. R., 75, p. 690) includes grub in the head of sheep (sheep botfly) as the cause of nasal discharge, by C. W. Hickman; a study of the methods of eradication of pullorum disease, paratyphoid in turkeys (see page 858, and the cause and control of foul sheath in rams, all by W. V. Halversen; and the establishment of resistance of flocks to fowl paralysis (E. S. R., 76, p. 107) and the reduction of high mortality by selective breeding, both by C. E. Lampman.

[Report of work in animal pathology by the Kentucky Station] (*Kentucky Sta. Rpt.* 1936, pt. 1, pp. 18-21).—The occurrence of and work with (E. S. R., 76, p. 97) an epizootic or virus abortion in mares (E. S. R., 77, p. 102), paratyphoid of pigeons due to *Salmonella aertrycke*, isolation of *S. newport* from a fatal case of hemorrhagic enteritis in feeder cattle, identification of *S. oranienburg* from quail in Illinois and *S. senftenberg* from poults in New Jersey, tests of aseptically drawn milk for the presence of *Brucella abortus*, and grass tetany (E. S. R., 77, p. 103) are considered.

[Contributions on animal pathology] (*Ontario Vet. Col. Rpts.*, 1934-35, pp. 10; 1935, pp. 13-32, figs. 5).—The first of these reports (E. S. R., 74, p. 99), covering the period November 1, 1934, to March 31, 1935, deals with the progress of the work with parasites and infectious diseases of livestock, by C. D. McGilvray; the second, covering the period April 1, 1935, to March 31, 1936, includes the following contributions: Breeding Difficulties in a Dairy Herd (pp. 13-15) and Outbreak of Depraved Appetite in Cattle (pp. 15, 16), both by R. A. McIntosh; Swine Plague (pp. 16-18), by T. L. Jones; Botryomycosis (pp. 18-20), Equine Encephalomyelitis (pp. 20-22), Pulpy Kidney Disease of Lambs (pp. 22, 23), and Malignant Diphtheretic Vaginitis of Cattle (pp. 23, 24), all by F. W. Schofield; Tuberculosis in Fur Bearing Animals (pp. 24-27) and The Control of the Flesh Fly, *Wohlfahrtia rigil*, and Other Flies (pp. 27-31), both by A. A. Kingscote; and Zoology in Relation to Veterinary Science (pp. 31, 32), by H. E. Batt.

[Studies in comparative pathology, etc., in Japan] (*Jour. Japan. Soc. Vet. Sci.*, 15 (1936), Nos. 2, pp. 128-163, figs. 8, pp. 23-29; 3, pp. 165-218, pls. 4, figs. 7, pp. 31-40; 4, pp. 219-221, 233-347, pls. 5, figs. 4, pp. 41-63, 66-84, pls. 4, figs. 3).—The contributions presented in No. 2 (E. S. R., 76, p. 244) are: Studies on the Purification of Mallein—III, Chemical Analysis of Glanders Bacillus and Proteins Obtained From Its Culture, as Well as Its Nitrogen and Carbohydrate Metabolism, by M. Umezu (pp. 128-142, Eng. abs. pp. 23, 24) (E. S. R., 71, p. 97); Complement-Fixation Reaction in Rinderpest—II, On the Thermolability of the Antiserum, by J. Nakamura (pp. 143-158, Eng. abs. pp. 25-27) (E. S. R., 62, p. 260); and A Case of the Infection With *Bacillus abortus equi* in Man, by S. Fujimura and T. Hoshi (pp. 159-163, Eng. abs. pp. 28, 29).

Contributions in No. 3 are: On the Pathogenicity of Several Strains of Tubercle Bacilli for the Rabbit When Inoculated Separately or Jointly Into the Anterior Chamber of the Eye, by Y. Miyamoto and T. Shimazaki (pp. 165-173, Eng. abs. pp. 31, 32); Investigations on Immune Isoreactions of the Blood of Korean Cattle, II [trans. title], by J. Nakamura and N. Tomonaga (pp. 174-189, Ger. abs. pp. 33, 34) (E. S. R., 64, p. 771); Complement-Fixation Reaction in Rinderpest—III, Antigenic Properties of Pest and Normal Lymphatic Glands, by J. Nakamura (pp. 190-200, Eng. abs. pp. 35, 36) (see above); On the Formosan Chicken Mite *Neoschongastia gallinarum* (Hatori 1920), by M. Sugimoto (pp. 201-213, Eng. abs. pp. 37, 38); and A Primary Carcinoma in the Liver of a Foetus, by H. Oguni and T. Ishida (pp. 214-218, Eng. abs. pp. 39, 40).

Contributions in No. 4 include: On the Epidemic Equine Encephalitis Which Occurred in the Year 1935 in Japan, by O. Emoto, S. Kondo, and M. Watanabe (Japan. abs. pp. 219-221, Eng. pp. 41-63); The Relation Between Diet and Trichina-Infection in Rats, by I. Motomura and M. Umezu (pp. 233-244, Eng. abs. pp. 66, 67); The Prevention and Treatment of Avian Coccidiosis, Particularly Through the Use of Jodinol [trans. title], by M. Yosikawa (pp. 245-261, Ger. abs. pp. 68, 69); Animal Experiments With the Scab-Virus of Sheep-Pox With Special Reference to Its Vaccinization, by S. Akazawa (pp. 262-276, Eng. abs. pp. 70-72); Abortion of Swine Due to *B[rucella] abortus suis*, by S. Nohmi, M. Katow, and S. Karasawa (pp. 277-285, Eng. abs. pp. 73-75); Studies on Contagious Abortion in Sheep—I, Outbreak of Contagious Abortion Among Ewes and of Malta Fever Among Veterinarians and Shepherds at the Rinsi Sheep-Farm in Rinsi (Inner Mongolia), by M. Itabashi and S. Watanabe (pp. 286-295, Eng. abs. pp. 76, 77); On the Colony-Type of *Streptococcus equi*—I, The Comparison of the Morphological, Cultural, and Biological Characters Between 3 Isolated Colony-Types, by S. Umeno (pp. 296-318, Eng. abs. pp. 78-81); and Experimental Studies on the Infectious Abortion in Mares—IV, Serological Observations, by K. Hirato (pp. 319-347, Eng. abs. pp. 82-84) (E. S. R., 76, p. 244).

p-Aminobenzenesulphonamide in bacterial meningitis, H. PROOM and G. A. H. BUTTLE (*Lancet* [London], 1937, I, No. 11, p. 661).—It is pointed out that by applying the chemical method described by Fuller (below) for the detection of *p*-aminobenzenesulfonamide (sulfonamide) in the blood and urine of treated animals it is possible to show that, when given orally, it appears in the cerebrospinal fluid in remarkably high concentrations. Reference is made to a rabbit administered sulfonamide by mouth, in which the concentration of the drug found 4 hr. later in the cerebrospinal fluid was 1 in 5,000. It is noted that this has been shown to be sufficient to exert a strong bactericidal effect on the streptococcus in *in vitro* experiments with human blood and on the meningococcus in culture medium, and illustrates the remarkable ease with which the drug diffuses through the body. This appears to justify its oral administration in the treatment of bacterial meningitis.

Is *p*-aminobenzenesulphonamide the active agent in Prontosil therapy? A. T. FULLER (*Lancet* [London], 1937, I, No. 4, pp. 194-198).—It is pointed out that both Prontosil and *p*-aminobenzenesulfonamide (sulfanilamide) have a protective action against infection by hemolytic streptococci. A considerable amount of sulfanilamide having been found to be excreted when Prontosil is administered by mouth or by injection, it is considered quite possible that the therapeutic action of Prontosil is due to the sulfanilamide derived from it by reduction in the body.

The presence of agglutinins for *Brucella abortus* in milk, H. B. MORRISON and F. E. HULL (*Kentucky Sta. Bul.* 369 (1937), pp. 29-43).—The determination of the presence or absence of agglutinins for *B. abortus* in 448 samples of milk from separate quarters of the udders of 99 Bang's disease positive cows and 699 similar samples from 132 Bang's disease negative cows in the station and two large commercial dairy herds is reported upon. Of these 448 samples, 51 percent were negative and 19 percent showed partial and 30 percent complete agglutination at a dilution of 1:50. "The milk of 36 percent of the Bang's disease reactors gave no agglutination at 1:50 dilution, that of 5 percent showed partial, that of 19 percent showed complete agglutination, and the milk of 40 percent showed differences in titer from different quarters of the udder. The milk of 45 percent of the reactors, from one or more quarters of the udder, gave complete agglutination; that from 20 percent gave partial agglutination only. When milk from only one quarter was agglutinated the agglutination was very seldom complete. Milk samples taken at different times from the same quarter of the udder of the same cow showed considerable difference in agglutinin titer. The percentage of agglutinations was slightly higher in milk from the hindquarters of the udder than in that from the forequarters, and complete agglutinations occurred oftener in milk from the hindquarters than in that from the forequarters (33 and 26 percent). Difference in percentage of agglutinations in milk from right and left halves of the udder was not material (30 and 29 percent). In only one sample out of 699 (0.14 percent) did milk from Bang's disease negative cows show any agglutination. In this instance the agglutination was only about 25 percent complete at a dilution of 1:50."

The details are given in 8 tables, and a bibliography of 12 titles is included.

Studies on hemorrhagic septicemia, J. B. TAYLOR (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 182-185).—This contribution from the South Dakota Experiment Station reports upon a study made of a buffalo strain obtained from the U. S. D. A. Bureau of Animal Industry and known as culture Buffalo B, belonging to Jones' group III, which produces exotoxin and endotoxin.

"A toxoid was developed by treating toxin with formalin and precipitating with acetone. Toxoid, aggressin, and bacterins failed to produce an immunity in rabbits sufficient to protect against injection of Buffalo B strain. The various strains of the *Pasteurella* group are not soluble in bile, saponin, sodium oleate, cholesterol, sodium ricinoleate, or sodium desoxycholate. Sodium bicarbonate and neocarsphenamine had no effect on the progress of the disease when injected intravenously. Strains of hemorrhagic septicemia isolated from various animals are rarely pathogenic for rabbits except for a few strains. Those isolated from cases of fowl cholera were always pathogenic for rabbits. Hemorrhagic septicemia is not a common disease, with the exception of fowl cholera."

Phagocytic activity of circulating cells in the various types of leukemia, M. M. STREUMIA and F. BOEBNER (*Amer. Jour. Path.*, 13 (1937), No. 3, pp. 335-350, pl. 1).—A study aimed at the determination of the variations, if any, in the phagocytic activity of cells found circulating in the various forms of leukemia, as well as in normal blood, and the establishment of a physiological criterion for differentiation in addition to those well known morphologically.

Relation of bovine mastitis to human disease, P. B. BROOKS and W. VON D. TIEDEMAN (*Amer. Jour. Pub. Health*, 27 (1937), No. 4, pp. 334-338).—This discussion is presented with a list of 14 references to the literature.

The Rickettsia diseases: Varieties, epidemiology, and geographical distribution, H. ZINSSER (*Amer. Jour. Hyg.*, 25 (1937), No. 3, pp. 430-463,

figs. 4).—A review, presented with a list of more than 120 references to the literature.

The antigenic structure and classification of members of the *Salmonella* group [trans. title], G. HORNUS (*Rev. Immunol.*, 1 (1935), No. 5, pp. 488-500).—This contribution to the classification of the *Salmonella* group is accompanied by 43 references to the literature. Particular mention is made of the work of P. B. White and of F. Kauffmann. See also a previous note (*E. S. R.*, 72, p. 534).

Sporadic *Salmonella* infections, with a case report, J. H. FISHER (*Lancet* [London], 1937, I, No. 11, pp. 623-625).—A sporadic case of *S. aertrycke* infection in man is reported. This organism, which frequently affects domestic animals, is the one most commonly responsible for food poisoning in England.

Salmonella suipestifer infection in human beings: Review of the literature and report of twenty-one new cases, A. M. HARVEY (*Arch. Int. Med.*, 59 (1937), No. 1, pp. 118-135).—This review of the literature relating to hog cholera bacillus infection in man is presented with a list of 57 references.

The present status of the practical control of streptococci in certified milk, W. D. FROST (*Amer. Assoc. Med. Milk Comms. [etc.]*, Proc., 25-28 (1932-35), pp. 44-47).—A contribution presented at the conference of the American Association of Medical Milk Commissioners and the Certified Milk Producers' Association of America held in May 1932 in Washington, D. C.

Studies on the differentiation of hemolytic streptococci, P. R. EDWARDS (*Amer. Assoc. Med. Milk Comms. [etc.]*, Proc., 25-28 (1932-35), pp. 47-50).—A practical contribution presented at the conference referred to above.

Studies on active acquired resistance, natural and artificial, in the rat to infection with *Strongyloides ratti*, A. J. SHELDON (*Amer. Jour. Hyg.*, 25 (1937), No. 1, pp. 53-65).—In quantitative studies on acquired resistance in rats to infection with *S. ratti*, here reported, it was found that they could be successfully immunized by serial infections, using small doses of infective larvae. This resistance was as effective in preventing reinfection at 30 days as it was a few days after the last immunizing infection. An almost absolute resistance was demonstrated to be acquired and retained by rats as the result of a single previous infection which had been allowed to run its normal course and disappear. Rats could be successfully immunized against infection with *S. ratti* by serial injections of heat-killed larvae in a saline suspension. Animals which had received 13 such injections at 3-day intervals (10 of 1,000 and 3 of 2,000 larvae) were as refractory to test infections as were animals immunized by previous or existing infections.

A list is given of 17 references to the literature.

Some experimental studies on *Strongyloides ratti*, A. J. SHELDON (*Amer. Jour. Hyg.*, 25 (1937), No. 1, pp. 39-52, figs. 2).—Quantitative data on some of the technical aspects involved in studies on *S. ratti* in the laboratory rat and certain of the biological relations between this parasite and its host are presented. The results indicate that consistently high percentages of development (22.1 on the average) can be obtained by subcutaneous infection of rats with larvae which have been cultured at 24° C. for 48 hr. and isolated in the Baermann apparatus for 45 min. The use of the daily larval output to measure the size of infection is shown to be impractical. An autopsy method by which an accurate count of the worms in the intestine of the rat can be made is suggested as being more satisfactory. A report is made of some of the biological relations determined by the experiments.

The localization of *Trichinella spiralis* in the muscle of its host, C. H. SCHEFFLEY (*Amer. Jour. Hyg.*, 25 (1937), No. 2, pp. 349-353).—A study of the

probable factors involved in the remarkable specificity in localization of the nematode parasite *T. spiralis* in muscle has shown that the diaphragm is more heavily infested than the muscles of the extremities. Complete unilateral lumbar sympathectomy with its resultant increased blood flow produced no significant change in the degree of localization in the operated limb as compared with the normal limb.

A study of the effect of age, weight, sex, and dose on the length of survival of albino rats infected with *Trypanosoma equiperdum*, with particular reference to variations in the host, C. A. MORRELL, C. W. CHAPMAN, and M. G. ALLMARK (*Amer. Jour. Hyg.*, 25 (1937), No. 2, pp. 232-258, figs. 9).—This is a report of the effect of dosage in *T. equiperdum* infections in the white rat and of sex, age, and weight of the host on the duration of the disease and the rate of increase of the parasites in the blood.

Studies on bovine blood.—I, The sedimentation rate and percentage volume of erythrocytes in normal blood, L. C. FERGUSON (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 163-175, figs. 2).—The results of sedimentation studies of the red blood corpuscles of 22 cows, including the sedimentation rate and percentage volume, are reported. The mean sedimentation index of this herd of cattle, calculated from the individual means, is 2.394 mm, with a standard deviation of 0.275 mm, a value of over 4 mm being indicative of pathology. "The mean percentage volume of erythrocytes, calculated from the individual means, is 31.32 percent, with a standard deviation of 2.184 percent. The results of analysis of variance with both the sedimentation index and the percentage volume indicate a highly significant difference between individuals as compared to that within individuals. The correlation coefficients of the sedimentation index and the percentage volume of erythrocytes possibly indicate a significant negative correlation. The relatively high fibrin content of normal bovine serum may account for the slow sedimentation rate.

"Since the sedimentation rate is increased in certain pathological conditions, application of the sedimentation test and percentage volume determinations may be of practical value as an aid in diagnosis and prognosis of certain cattle diseases."

Further observations on staphylococcal infections of the bovine udder, R. GWATKIN (*Canad. Pub. Health Jour.*, 28 (1937), No. 4, pp. 185-191).—A report is made on 19 cases of mastitis, apparently due to staphylococci, that were detected during the examination of 260 cows. One hundred and ninety of the 275 strains of *Staphylococcus pyogenes* fermented mannitol, and 85 were negative. Twenty-four positive (12.5 percent) and 60 percent of the negative strains were recovered from apparently normal udders. Forty of 65 strains of staphylococci showed some degree of zone production on Stone's beef extract-gelatin-agar plates, and 11 of these liquefied Stone's beef extract-gelatin. Seventeen kittens were given intraperitoneal injections of 3 cc of boiled filtrates of some of these strains, and 7 of them showed some gastrointestinal symptoms, in one case severe. Agglutination and complement-fixation tests on blood serum and whey from streptococcal and staphylococcal cases were negative.

Pulmonary coccidioidal granuloma: A new site of infection in cattle, C. L. DAVIS, G. W. STILES, JR., and A. N. MCGREGOR (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 209-215, figs. 6).—Pulmonary lesions in bovine coccidioidal granuloma are reported for the first time, 47 new bovine cases having been observed. A survey of additional cases of coccidioidal granuloma in both man and animals continues to show a decided concentration of the disease in the San Joaquin Valley in California.

The occurrence of *Onchocerca gutturosa* Neumann in cattle in England, with an account of its life history and development in *Simulium ornatum* Mg., J. S. STEWARD (*Parasitology*, 29 (1937), No. 2, pp. 212-219, pl. 1).—The occurrence of *Onchocerca* in English-bred cattle is recorded for the first time. A specific diagnosis of *O. gutturosa* is made, *O. bovis* being regarded as a synonym.

"The microfilariae occur in the skin of infected cows, and blood-sucking flies of the genus *Simulium* were found to be the vectors. Complete development was observed in *S. ornatum* and partial development in *S. erythrocephalum*. *S. ornatum* appears to be a very efficient intermediary host, as over 40 percent became infected. *Culicoides nubeculosus*, the vector of *O. cervicalis* of horses, does not appear to carry the bovine *Onchocerca*."

Rickettsia bovis: A new species pathogenic for the bovine [trans. title], A. DONATIEN and F. LESTOQUARD (*Bul. Soc. Path. Exot.*, 29 (1936), No. 10, pp. 1057-1061).—A parasite of the monocytes transmitted by ticks of the genus *Hyalomma* in Iran, where it is the cause of a mild affection that results in a premunition of the host, is described as new under the name *R. bovis*.

A morphological study of bovine schistosomes, L. VAN DEN BERGHE (*Jour. Helminthol.*, 15 (1937), No. 2, pp. 125-132, pl. 1, fig. 1).—In reporting upon a morphological study of the bovine schistosomes from the Belgian Congo the author has relegated the species *Schistosoma mattheei* to the rank of a variety of *S. bovis*. In view of the morphological relationships existing among the four schistosomes—*S. haematobium*, *S. intercalatum*, *S. mattheei*, and *S. bovis*, he was led to conclude that these constitute biological races of a single species.

[Report of work with bighead in sheep], A. B. CLAWSON and W. T. HUFFMAN (*Natl. Wool Grower*, 25 (1935), No. 1, pp. 18-20, figs. 3; 26 (1936), No. 1, pp. 18-21, figs. 5; 27 (1937), No. 3, pp. 13-16, figs. 5).—Work aimed at the determination of the cause or causes of the serious losses of sheep from bighead occurring in the Intermountain States, particularly in Utah, Nevada, eastern Oregon, and southern Idaho, commenced in March 1934 and carried on by the U. S. D. A. Bureau of Animal Industry, is reported upon.

Feeding experiments have shown that (1) the so-called coal oil brush or littleleaf horsebrush (*Tetradymia glabrata*), which is present on most of the principal grazing areas of Utah, the southwestern and northeastern corners excepted, and occurs in certain areas in Nevada, Oregon, and Idaho, and (2) the spineless horsebrush (*T. canescens* or *T. canescens inermis*), which occupies most of the bighead areas in central and eastern Nevada, northeastern and southwestern Utah, most of Idaho except the southwestern portion, as well as southwestern Wyoming and southwestern Montana, are the sources of this affection. The bighead areas were found to be almost identical with the habitat of these two plants.

The evidence obtained indicates that throughout the regions studied the serious outbreaks have occurred in or very shortly after the sheep have passed through areas where one or the other of these plants was abundant, and that the conditions were favorable for the eating of them.

Mortality in sheep due to the ingestion of the foliage of myall trees (*Acacia pendula*) infested with the boree moth *Teara contraria*, W. L. HINDMARSH (*Austral. Vet. Jour.*, 13 (1937), No. 3, pp. 124, 125).—The inflammatory lesions of the abomasum and small intestine of sheep fed on the foliage of the myall, a valuable drought fodder tree relished by sheep in the drier parts of New South Wales, are considered to have been due to irritation caused by the hairs of caterpillars of the boree moth *T. contraria*.

Occurrence of a conjunctivitis of sheep in Algeria due to *Rickettsia conjunctivae* Coles 1931 [trans. title], A. DONATIEN and F. LESTOQUARD (*Bul. Soc. Path. Exot.*, 30 (1937), No. 1, pp. 18-20).—Report is made of a contagious conjunctivitis in sheep, caused by *R. conjunctivae* and at times widespread in Algeria.

Sheep scab: Remedial measures reviewed, E. A. LEWIS (*Bul. Ent. Res.*, 28 (1937), No. 1, pp. 11-30, pl. 1).—This review is presented, with a list of 21 references to the literature.

Sheep myiasis in south-west Scotland, with special reference to the species involved, A. J. HADDOW and R. C. MUIRHEAD THOMSON (*Parasitology*, 29 (1937), No. 1, pp. 96-116, figs. 3).—In the investigation of myiasis in certain districts of southwest Scotland, larvae from sheep were collected and reared in flyproof apparatus. The fly season was found to last approximately from May to September, reaching its height in July and August. The flies were found to be partial to low-lying, sheltered ground, especially where much bracken was present. The hibernation of various species was studied, and they were found to pass the winter as prepupae, pupation never occurring until April or May. "Several species of carrion-feeding blowfly besides *Lucilia sericata* were found to be causing secondary myiasis, occasionally and in small numbers, in certain districts, mainly in the west. The species involved were *L. caesar*, *L. illustris*, *Protophormia terraenovae*, *Galliphora erythrocephala*, *C. vomitoria*, and *Muscina pabulorum*. Four of these species, *L. illustris*, *P. terraenovae*, *C. vomitoria*, and *M. pabulorum*, have not previously been recorded from sheep. Records of cases in which these flies occurred are given."

A study of *Spirochaeta penortha* (n. sp.) isolated from foot-rot in sheep, W. I. B. BEVERIDGE (*Austral. Jour. Expt. Biol. and Med. Sci.*, 14 (1936), No. 4, pp. 307-318, figs. 8).—The organism recorded by the author in 1935 (*E. S. R.*, 74, p. 855) as being constantly present in foot-rot lesions has been isolated in pure culture, its morphology, cultural characters, and pathogenicity for experimental animals being described. "It grows in a medium commonly used for the cultivation of spirochetes, but more rapidly and abundantly in culture media containing raw potato. Cultures are almost devoid of pathogenicity for experimental animals. Specific agglutination was demonstrated in high dilution with prepared antisera. Although typically the organism lacks discernible spirals, its other characteristics necessitate its classification as a spirochete. The name *S. penortha* is proposed. It is possibly identical with *Treponema podovis*, already described in foot-rot lesions, but it does not agree with descriptions of that organism."

Pseudotuberculosis of deer, H. HAMMERSLAND and E. M. JONESCHILD (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 186-192, fig. 1).—Experiments in which eight guinea pigs, three rabbits, two chickens, one dog, and a mouse were inoculated with suspensions of *Corynebacterium ovis* are reported. Guinea pigs, rabbits, and mice were found to be susceptible, and chickens and dogs apparently not susceptible to this organism. The percentage of infection was found to be small in deer compared to that in sheep. "All transmission experiments and cultural morphological characteristics classify this organism found in deer to be that of the species *C. ovis*."

Renguera, J. F. MITCHELL (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 176-181, figs. 2).—An account is given of renguera, also known as paraplegia enzootica (Span.), paraplegia enzootique des agneaux (Fr.), louping ill, and swing-back, a paraplegia of lambs, kids, llamas, alpacas, and vicunas caused by a filtrable, infectious, and inoculable virus which attacks the cen-

tral nervous system, causing locomotor ataxia. It was first studied in 1911 during an outbreak which occurred around Cerro de Pasco in central Peru, in which about 90 percent of the lambs died. In a fifth outbreak in December 1936, and now in progress, about 30 percent of the lambs were attacked.

The susceptibility of hogs to red squill, J. C. WARD, C. W. BARBER, F. E. GARLOUGH, and J. C. MUNCH (*Jour. Amer. Pharm. Assoc.*, 26 (1937), No. 2, pp. 137-139, figs. 2).—Reports of animal losses, particularly hogs, presumably caused by the consumption of red squill baits exposed for rat control, led to the tests here reported. Animals purchased on the Denver, Colo., market, after having been proved to be normal, were starved from 24 to 72 hr. and then fed varying amounts of red squill powder and of extract. The powder was found to be lethal when administered by stomach tube in doses of 175 mg per kilogram of weight and above. Red squill extract was lethal to hogs when given by stomach in doses of 500 mg per kilogram. Most hogs will not eat enough red squill rat poison voluntarily to cause death. The red squill powder causes emesis in hogs, which tends to protect the animals when baits are consumed normally.

The physiology of digestion in larvae of *Gastrophilus equi*, D. N. ROY (*Parasitology*, 29 (1937), No. 2, pp. 150-162).—In reporting upon the physiology of digestion of the horse botfly in the horse, it is pointed out that horses do not show any symptoms even when there is a heavy infestation because the larva does not feed on blood but lives on the fluid material partly digested by its host in the stomach.

A relationship in equines between age of host and number of strongylid parasites, A. O. FOSTER (*Amer. Jour. Hyg.*, 25 (1937), No. 1, pp. 66-75, fig. 1).—During quantitative studies in the Panama Canal Zone of the worm burdens of 86 equines, varying in age from 9 to 30 yr., it was found that "from 59 animals, 15 yr. and under, there was recovered an average of 1,219 worms per animal as compared to an average of 502 worms from 27 animals over 15 yr. This was interpreted as an age resistance of equines against strongylid parasites and was demonstrated quantitatively for the commoner individual species. In the instances of *S[trongylus] vulgaris*, however, the data afforded no evidence of increased protection in the older animals. This was considered significant in view of the importance of the parasite. In addition, it was concluded that in the data of the present studies there was no evidence of an age resistance of equines against stomach worms."

Researches on *Rickettsia canis*: A comparison with *R. conori* [trans. title], A. DONATIEN and F. LESTOQUARD (*Bul. Soc. Path. Exot.*, 29 (1936), No. 10, pp. 1052-1056).—Epizootiological observations and experimental inoculations with emulsified ticks indicate that the brown dog tick serves as an agent in the transmission of *R. canis*. *R. canis* and *R. conori* are considered to represent two distinct species. *R. canis* has been observed not only in Algeria but also in France along the Mediterranean coast.

The histopathology of natural and experimental canine distemper, W. A. DEMONBREUN (*Amer. Jour. Path.*, 13 (1937), No. 2, pp. 187-212, pls. 5).—A review of work on canine distemper is given with a list of 30 references. The lesions believed to be characteristic of the disease are described.

"The virus of canine distemper has a definite affinity for vascular endothelium and for cells of the reticulo-endothelial system. The virus spreads in the body of the host mainly by way of the blood stream. We have obtained no evidence that it passes along the nerve pathways. The natural route of infection is by way of the respiratory tract. The occurrence of nuclear inclusions, heretofore unreported, in liver cells, bronchial epithelial cells, glandular

cells of the stomach and intestine, and bile duct epithelial cells, and cytoplasmic inclusions in bile duct epithelial cells are described. A heretofore unreported clinical type of the disease with a characteristic microscopic pathology is described and has been reproduced in puppies. Various clinical types of the disease have been induced in puppies with a single strain of virus. The histopathology and cytology of the disease in dogs and ferrets are quite similar."

The toxicity of *Crotalaria retusa* L. seeds for the domestic fowl, M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 205, 206).—In an experiment at the Florida Experiment Station force feeding Leghorn hens with single doses of 100 *C. retusa* seeds caused death within 14 days and single doses of 200 seeds caused death within 10 days. Chronic cases of poisoning were induced by force feeding 10 seeds every other day, death occurring in from 18 to 40 days. In five birds fed a grain mixture containing seeds of *C. retusa* scattered on the ground once a day, death occurred in from 15 to 32 days.

[Work with diseases of fowl by the Massachusetts Station] (*Massachusetts Sta. Bul.* 339 (1937), pp. 87–90).—In this report of the year (E. S. R., 75, p. 537) brief reference is made by H. Van Roekel, K. L. Bullis, O. S. Flint, and M. K. Clarke to the progress of pullorum disease eradication (E. S. R., 76, p. 107), antigenicity studies of *Salmonella pullorum* strains, its viability, the whole blood agglutination test, maltose-fermenting *S. pullorum* strains, pullorum disease in turkeys (encountered in two flocks during the year), disease studies of ruffed grouse and paratyphoid infection in young pheasants, diagnosis of ulcerative enteritis of turkeys and of an organism resembling *Erysipelothrix rhusiopathiae*, flock mortality studies, and epidemic tremor in chicks.

[Work with avian diseases by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1936], pp. 39, 40).—A brief report is made of the work of the year (E. S. R., 75, p. 849) with infectious rhinitis (coryza), in which during the course of studies of *Hemophilus gallinarum* (E. S. R., 75, p. 547) a secondary micro-organism, *Shigella nasalis*, was isolated from infected chicks; infectious bronchitis; leucosis; and cerebral disorder of chicks.

The problem of infection as presented by bacterial invasion of the chorioallantoic membrane of chick embryos, E. W. GOODPASTURE and K. ANDERSON (*Amer. Jour. Path.*, 13 (1937), No. 2, pp. 149–174, pls. 4).—The authors have found the inoculation of the chorioallantoic membrane of chick embryos with pure cultures of pathogenic bacteria to be a practical method for studying many problems of infection, especially the early stages of invasion. "Many pathogenic bacteria find in either mesodermal cells (fixed or mobile) or epithelial cells, or both, favorable and possibly necessary media for invasion of the living host. In these instances phagocytosis, instead of representing resistance to infection, actually favors it. Among those pathogenic bacteria that are able to utilize a living intracellular environment for growth are *Str[eptococcus] viridans*, *A[erobacter] aerogenes*, *E[berthella] typhi*, *Br[ucella] abortus*, and *Mycobacterium tuberculosis avium*. *Staph[ylococcus] aureus* and *Str[eptococcus] hemolyticus* may be in part destroyed by the phagocytes of the embryo, and they appear to be incapable of growing in an intracellular medium in this host."

Fowl leukosis, C. D. LEE, H. L. WILCKE, C. MURRAY, and E. W. HENDERSON (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 146–162).—This contribution includes the results of seven transmission experiments with fowl leukosis, which term is used to include in common the group of leukemic, aleukemic, and

leukemiclike diseases of fowl. Young chicks have been found to be more susceptible than older ones, with the greatest incidence between the ages of 2 and 12 mo., the majority of cases occurring between 4 and 10 mo.

"The disease in all of its expressions may be transmitted to healthy chicks by injection of tissue suspensions of affected tissues or by injection of cell-free filtrates. It may be transmitted by direct pen contact or by rearing chicks on contaminated litter. Neurolymphomatosis gallinarum, associated with eye lesions, hemocytoblastosis, lymphoid, erythroid, and myeloid types of leucosis are different expressions of the same disease and were transmitted by a common etiological agent. Erythroleucosis and myeloid leucosis manifestations are largely dependent upon involvement of the bone marrow. The lesions may be localized in one area or may be generalized. The injection of a suspension made from one type apparently produces practically all the various types considered as expressions of this disease. Different suspensions were used in all groups of the experiment, but practically the same results were obtained in each group. The incidence is often very high in spontaneous infected flocks. The lesions may be confined to one or more types of tissue in some cases and to some other type or types in other cases. Breed and sex differences apparently do not affect the incidence of the disease. There appears to be an inherent difference of susceptibility and resistance by different birds and birds of different strains. The disease spreads rather slowly in infected flocks, and only a few birds are clinically affected at one time. There seems to be some evidence to suggest that the disease may be transmitted through the egg to a limited extent. The evidence indicates that fowl leucosis is an infectious disease, and the transmissible agent is a filtrable virus. The clinical course is variable, extending over a period of weeks or months in some cases, while in others it is comparatively short. No complete recoveries occur, although temporary respite from the disease have been noted.

"This disease is one of the most important diseases confronting the poultry industry. The most important methods of control are proper sanitation and the use of breeding stock from resistant sources."

A list is given of 37 references to the literature.

Transmissible splenomegaly of fowls or reticulo-endothelial leucosis ("erythroleucosis"), H. P. BAYON (*Roy. Soc. Med. [London], Proc., 30 (1937), No. 4, pp. 377-384*).—Following a review of previous investigations abroad, presented with a list of 25 references to the literature, the author's observations on splenomegaly in fowls in Great Britain are reported.

"In fowls from different parts of England a deadly disease has been observed which is characterized by the appearance of a dark swollen liver and a much-enlarged spleen; the blood was found to contain an increased number of immature monocytes. Histological examination of the internal organs showed that the condition was due to a diffuse proliferation of the reticuloendothelial system of the liver, spleen, and bone marrow; at times lungs and ovary were involved. Kidney might also be affected, but here enlargement seemed to be due to an invasion by monoblastlike cells. Nerves were not found infiltrated, the type of cell in this ailment differing from that involved in neurolymphomatosis gallinarum. The disease could be accurately named 'reticuloendothelial leucosis', since anemia is not an outstanding or primary feature; at no time are large numbers of immature erythrocytes or even erythroblasts detectable in the blood, as in yellow anemia or erythromyelosis. The invasion of the blood by immature monocytes or monoblasts occurs in later stages and is preceded by hypertrophy of the hepatic and splenic reticuloendothelium.

"These investigations not only confirm the independent origin of erythrocytes and lymphocytes in fowls, but also indicate that monocytes arise in the reticuloendothelium of the marrow, spleen, and liver, and differ in behavior from histiocytes. The identity of the disease observed in England with that described as erythroleucosis on the Continent has been ascertained by obtaining virus from Budapest and then comparing the lesions obtained by the inoculation of this virus with those observed in this country, either in the field or after inoculation with tissues of leucotic fowls from Dorset. . . .

"The term 'leucosis' might be reserved for those conditions, occurring in birds and other animals, in which the morbid condition consists in the primary proliferation of lymphoidal cells (monoblasts or histiocytic cells) in the tissues, with their secondary invasion of the circulation as monocytes or blood histiocytes."

Studies on oöcyst production in avian coccidiosis, I, II, D. C. BOUGHTON (*Amer. Jour. Hyg.*, 25 (1937), No. 2, pp. 187-211).—In the first (pp. 187-202) of the two contributions here presented, a technic for counting the oöcysts of avian coccidia which consists essentially of dilution counts on suspensions of dried feces is described. Single counts readily differentiate the various levels of oöcyst production encountered in natural and experimental infections. Dried samples can be stored conveniently and do not deteriorate. The counting technic is capable of demonstrating parasite populations (*Isospora* in English sparrows) of a markedly lower order than those which can be observed microscopically in avian malarías.

In the second contribution (pp. 203-211) chronic infections in the sparrow due to *Isospora* are considered.

Studies on oöcyst production in avian coccidiosis.—III, Periodicity in the oöcyst production of eimerian infections in the pigeon, D. C. BOUGHTON (*Jour. Parasitol.*, 23 (1937), No. 3, pp. 291-298).—Data on the findings in five pigeons, trapped in Boston in November 1933, confined as a group in the same cage, and on the findings when placed in separate cages, are reported in tables in this further contribution.

Sulfur in the control of external parasites of chickens.—Preliminary report, M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 201-204).—In an experiment at the Florida Experiment Station in which commercial laying mash containing 5 percent commercial flowers of sulfur was fed to hens, their infestation by lice (*Menopon stramineum* and *M. gallinae*) was considerably reduced at the end of 2 weeks and by the close of the third week none could be found. A similar result was obtained when the experiment was repeated. Infestations by the sticktight flea of fowls receiving such treatment augmented by sulfurizing the yards at the rate of 100 lb. of sulfur per 400 sq. ft. of area and placing a light coating of sulfur on the floor of the houses beneath the litter were brought under complete control in 3 weeks. Infestations on fowl tick-infested flocks were reduced, and reinfestation did not occur. Direct contact with sulfur was found to kill the adult flea in from 5 to 10 min. at room temperature. The chicken mite was controlled in several poultry houses by dusting the floors, dropping boards, and nests with sulfur.

An erysipelas outbreak in turkeys, D. E. MADSEN (*Jour. Amer. Vet. Med. Assoc.*, 91 (1937), No. 2, pp. 206-208).—This is a report by the Utah Experiment Station on the outbreak of erysipelas due to *Erysipelothrix rhusiopathiae* in a flock of 1,300 5½-month-old turkeys, which resulted in the death of 325 (25 percent).

Paratyphoid in turkeys, V. A. CHEERRINGTON, E. M. GILDOW, and P. MOORE (*Poultry Sci.*, 16 (1937), No. 4, pp. 226-231).—Contributing from the Idaho Ex-

periment Station, the authors report having found a *Salmonella aertrycke* type organism to be responsible for several outbreaks of paratyphoid in turkeys in widely separated localities in that State.

Paratyphoid infection of turkeys may be characterized as an endemic septicemic disease of poults. The poults died rapidly up to 10 days of age, with weakness and occasional diarrhea as the common symptoms. No outstanding diagnostic symptoms or lesions were present. Older poults were more chronically affected and responded to good hygienic and management practices. One-third to one-half of the hens in the breeding flocks that produced affected poults reacted when tested by the agglutination test with antigen made from the *S. aertrycke* type organism. One flock of hens producing paratyphoid-free poults did not show any reactors.

The *S. aertrycke* type organism was isolated from 3 out of 30 dead-in-the-shell poults cultured from one flock. The organism was not detected in 23 infertile eggs from the same flock. The causative organism was isolated from the ovaries of 2 out of 6 hens examined. These birds were from a flock in which 13 reacted out of 24 tested.

Attempts to eliminate the disease by fumigating the eggs in the incubator, by isolating the poults in sanitary quarters, and by the use of medication in the drinking water were not effective. Low vitality in the poults at hatching time and overheating them in the brooder house appeared to reduce their resistance to the infection and to raise the mortality rate. One lot of 38 poults brooded at the University in a battery brooder under good conditions showed a mortality of less than 50 percent up to 12 weeks of age. Poults from the same hatch, when brooded on the turkey farm, showed a mortality of approximately 90 percent. Clean 10-week-old poults brought in from outside sources and ranged with poults from the affected flock died extensively from paratyphoid infection.

The data accumulated in this study seem to indicate that the initial infection was present in the ovaries of the breeding hens; that it was transmitted to fertile eggs and directly to the poults that hatched from such eggs; and that the infection spread rapidly in the incubator and brooder to poults that were not infected at hatching time.

A list is given of 9 references to the literature.

The nematode *Ornithostrongylus quadriradiatus*, a parasite of the domesticated pigeon, E. CUVILLIER (*U. S. Dept. Agr., Tech. Bul. 569 (1937), pp. 36, figs. 6*).—A study is reported of the taxonomy, life history, host-parasite relations, and pathogenicity of the small roundworm *O. quadriradiatus*, which is associated with a serious disease and of which since 1930 there have been numerous outbreaks among pigeons in various parts of the world.

The taxonomic studies indicated "that *O. crami* Pérez Vigueras 1934, described from Cuba, is synonymous with *O. quadriradiatus*. Similar study of specimens from Panama revealed that they are less closely related to *O. quadriradiatus* than to *O. fariai* and that they probably belong to the latter species. They differ from *O. quadriradiatus* most markedly in length of the worms, size of the dorsal ray of the bursa, and spicule length. According to morphological observations, the spicule length of *O. quadriradiatus* does not vary markedly in specimens from different parts of the country nor in male worms of different ages.

"The life history was shown to be of the direct and simple type. Eggs in the 32- or 64-cell stage, when passed in the feces of the host, may hatch within 19 hr. under favorable conditions; a rhabditiform larvae emerges. The first-stage larva molts within about 8 hr., becoming the second-stage larva. The second

molt occurs usually on the third day, the larva then becoming filariform, ensheathed, and infective for the host. This third-stage larva may be distinguished by its dorsal and two subventral tail papillae. The fourth stage and the adult stage are passed within the intestine of the host; eggs may appear in its feces 5 to 6 days after infection."

The eggs were found to be nonresistant to drying and to a very low temperature; neither were the first- and second-stage larvae resistant to heat or drying. The third-stage larvae were killed by strong sunlight within a few hours. "Drying for 24 hr. killed a large percentage of infective larvae. Exposure to extreme cold for a short period, however, did not kill them. Placing them in water an inch deep killed the infective larvae, possibly because of decreased oxygen supply. Survival of larvae on soil, either shaded outdoors or in boxes in the laboratory, was considerably shorter in duration than that in water cultures in the laboratory. Infective larvae were observed to migrate laterally about 2 in. and vertically as much as 3 in. . . . Attempts to infect chickens, turkeys, and a duck were unsuccessful except for the development of 11 fourth-stage larvae in 1 chicken. . . .

"Control of this parasite should be based mainly on destruction of the pre-parasitic stages. This can be done effectively by drying and exposure to sunlight. It is advisable to separate immediately any infested birds."

A list is given of 40 references to the literature cited.

Toxoplasma in North American birds and attempted transmission to canaries and chickens, C. M. HERMAN (*Amer. Jour. Hyg.*, 25 (1937), No. 2, pp. 303-312, pl. 1).—In the study here reported, *Toxoplasma*, a genus of parasites which has been found in the white blood cells and lymphocytes of mammals and birds, has been detected in many species of passerine birds, having been found in Syracuse, N. Y., and Beltsville, Md., and on Cape Cod, Mass. It is suggested that only one species occurs in birds, for which *T. pallae* Herman, possibly synonymous with *T. gondi*, is believed to be the correct name. Attempted transmission from sparrows to canaries and to chickens resulted negatively.

A list of 27 references to the literature is given.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Idaho Station], H. BERRSFORD (*Idaho Sta. Bul.* 221 (1937), pp. 12-16, fig. 1).—The progress results are briefly presented of investigations on plow development for pea weevil control; high-speed combines and reel and bunching equipment for peas; alcohol-gasoline blends for engine fuel; farm building failures; earth type potato storage cellars; and rural electrification.

[Agricultural engineering investigations by the Massachusetts Station], C. I. GUNNESS ET AL. (*Massachusetts Sta. Bul.* 339 (1937), p. 8).—Progress results are briefly presented of investigations on low-lift pumps for cranberry bogs, milk cooling (with W. H. Tague), and cranberry storage.

Surface water supply of the United States, 1935, Parts 1, 2, 3 (*U. S. Geol. Survey, Water-Supply Papers* 781 (1937), pp. 421, pl. 1; 782 (1937), pp. 233, pl. 1; 783 (1937), pp. 400, pl. 1).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1935, No. 781 covering the North Atlantic slope basins; No. 782, the South Atlantic slope and eastern Gulf of Mexico basins; and No. 783, the Ohio River Basin.

Use of irrigation water on farm crops, A. E. PALMER (*Canada Dept. Agr. Pub.* 509 (1936), pp. 51, figs. 7).—The results of a large number of experiments

are reported which were conducted at the Dominion Experimental Station at Lethbridge, Alta. These were planned to determine the stage of plant growth when water should be applied to field crops, the value of fall irrigation, and the number of irrigations required in different years by various crops. Data are reported from experiments on the irrigation of wheat, alfalfa, potatoes, sugar beets, and sunflowers, covering a period of from 2 to 6 yr.

One irrigation produced a good crop of wheat in the years of average rainfall. In the drier seasons, two applications of water were needed. Irrigating in the fall after harvest for the succeeding year's wheat crop proved to be a good practice. If a fall irrigation was not given, and if the precipitation of May and early June was not abnormally high, it was found essential to irrigate after the crop was up in the spring but before the plants were checked in growth by lack of moisture. Contrary to the usual opinion, irrigating wheat as early as the three-leaf stage did not reduce yields on the sandy clay-loam soils where the experiments were conducted. When wheat needed more than one irrigation, good results were obtained when the second application was made in the flowering stage. Irrigating wheat in the soft-dough stage did not increase yields, but sometimes caused the grain to lodge.

In each year of the experiments, except the wet year of 1927, alfalfa required at least two irrigations to produce two good crops. It was found necessary to apply one of these the previous fall or in early May to give a heavy first cutting of hay. If May was dry, an irrigation when the first crop was about 12 in. high increased the yields. It seemed to make little difference in the yields of the second crop whether the water for the second irrigation was applied 10 days before or immediately after cutting the first crop.

Irish Cobbler potatoes, irrigated when the plants were half-grown, gave lower yields than if the first irrigation was postponed until the plants were starting to bloom. In the drier seasons an irrigation in the starting-bloom stage and two subsequent irrigations at intervals of 20 days was the most satisfactory practice. There was no consistent difference observable in the cooking quality of potatoes receiving different irrigation treatments. When the plants were retarded in growth from lack of water and then irrigated, second growths, resulting in knotty tubers, were prevalent. The potatoes receiving five or six irrigations produced tubers with enlarged lenticels, but the cooking quality did not appear to be impaired. The greater number of irrigations produced more small potatoes than one or two irrigations.

Sugar beets have given the best yields and the highest sugar content when the soil has been kept moist enough for maximum growth during the entire growing season. In dry years this has required irrigating as often as every 2 weeks from the first or second week of July to early September on loam soils.

Sunflowers gave best yields on fall-irrigated land or with a spring irrigation when the plants were about 6 in. high. In the 2 yr. of the test with sunflowers one irrigation in the season was sufficient. This crop wilted noticeably if the soil became too dry, but revived and produced fair yields when water was applied.

The experiments indicate that, including the available water in the soil at the beginning of the season, wheat requires from $1\frac{1}{2}$ to $1\frac{3}{4}$ acre-ft. of water, alfalfa from $1\frac{1}{4}$ to $2\frac{1}{4}$, and potatoes about $1\frac{1}{2}$ acre-ft. to produce good crops.

Soil moisture determinations made of each foot-depth of soil to a depth of 6 ft. before and after each irrigation showed that a 6-in. application of water failed to penetrate into the soil to a depth of 6 ft. in more than half the plats when the soil moisture content was below 11 percent at the time of

irrigation. With a moisture content between 11 and 13 percent, from 60 to 70 percent of the observations showed that the water had penetrated to 6 ft. The water applied to almost all of the plats having a soil moisture content above 13 percent wet down 6 ft. or more.

The loss of water from the soil of fall-irrigated land between the time of irrigating in the fall and seeding the following spring was noticeable but usually not important. However, in 1925-26 when the weather between mid-October and early May was very open, dry, and windy, the water loss from a number of plats was about equal to the irrigation application of the previous fall.

A study of influence of depth of ground-water level on yields of crops grown on peat lands, H. B. ROE (*Minnesota Sta. Bul. 330 (1936), pp. 32, figs. 9*).—Investigations are reported which were begun in 1925 and extended through the summer of 1930 to determine the degree of drainage that produced the best practical results with field and horticultural crops commonly grown on peat lands.

Depths of water table 1, 2, 3, 4, and 5 ft. below the surface were secured on definitely limited areas. Control was secured by an adjustable weir in the main tile line downstream from the plat, the water being fed into the soil by a loop of 4- or 5-in. drain tile surrounding the control plat, taking off from and ending in the main above the weir. Depth of water table was measured semiweekly throughout each season from the tops of test wells set in straight lines across each control area at intervals, and elevation of tops of test wells was redetermined several times each season. The data obtained showed control of the ground-water level by this method to be possible within practical limits at any desired depth below the surface, provided the peat is at least as deep as the desired water level, if there is an ample supply of underground water, and if potential settlement of the original bog surface is allowed for in the control works. Control, however, is relatively expensive and can be justified only in the case of special crops yielding a high return per acre.

Settling of the surface of the bog continued for several seasons after cultivation began. It was practically proportional to the depth of water table maintained on the different plats, and usually ranged from 6 in. to 2 ft. Such surface settlement is one of the principal factors determining proper depth of drains in a new bog if the depth of the peat is 4 ft. or more. Over any given control area the surface of the water table tended to remain flat; but heavy rainfall caused temporary upward arching between tile lines, while high water requirement by the plants during July and August depressed it.

The surface was packed with a heavy roller each season before seeding or planting. The packing is essential for satisfactory seed germination, and seems also to aid against summer frosts owing to better heat conductivity of the compacted peat. Fertilizer was applied as follows: 1925, over the entire tract, triple superphosphate at the rate of 400 lb. and muriate of potash at the rate of 200 lb. per acre; other years, for field crops nothing and for truck crops 16 percent superphosphate at the rate of 600 lb. and muriate of potash at the rate of 400 lb. per acre. Careful attention to the use of fertilizer is deemed essential on peat soils, but each bog is an individual problem. The crops raised included sugar beets, field corn, flax, oats, soybean, timothy, and clover hay, snap beans, sweet corn, onions, potatoes, tomatoes, carrots, summer radish, winter radish, cabbage, cauliflower, spinach, lettuce, and celery.

Summer frosts occurred nearly every summer and seriously affected yields of flax, field corn, beans, sweet corn, potatoes, and tomatoes. Soybeans, usually fairly resistant to frost, were seriously damaged by both June and August

frost. Frost damage was greater on the deeper controls owing to the poor heat conductance of the peat soil, indicating that as high a ground-water level as compatible with the crops to be raised is a desirable means of protection. Air drainage was poor, until a solid wall of timber and brush along two sides of the experimental tract was removed, after which summer frosts rarely occurred.

Flax did fairly well the first season, with best results at from 3- to 3½-ft. depth of ground water. It was a failure all other seasons, due largely to weed infestation, although also damaged by summer frosts. Oats was not a satisfactory crop any season at any depth of drainage. This is contrary to the usual experience with oats on peat except where lodging or severe rust occurs. Hay crops, such as soybeans, timothy, and clover, did well, with best yields where drainage was not over 2½ ft. deep after the bog had ceased to settle.

Spinach and head lettuce failed to give any satisfactory results. Failure of spinach, usually a reliable crop on peat soil, is not readily accounted for unless due to unseasonable planting. Climatic conditions in this region are not favorable for production of head lettuce.

After settling of the bog was complete, best results were generally obtained for all other crops in these tests with depths of water table from 3 to 3½ ft. This final average depth, after settlement is practically complete, is recommended where almost any type of crop may be tried at some time.

Soil erosion and stream flow on range and forest lands of the upper Rio Grande watershed in relation to land resources and human welfare, C. K. COOPERIDER and B. A. HENDRICKS (*U. S. Dept. Agr., Tech. Bul. 567 (1937), pp. 88, pls. 20, figs. 15*).—The results reported were secured at the Southwestern Forest and Range Experiment Station, maintained in cooperation with the University of Arizona. A general survey was made of the range and forest lands within the upper Rio Grande watershed, including the erosion conditions in Mesilla Valley, particularly the bordering range lands, below Elephant Butte Dam.

The lands of the Rio Grande watershed, which embraces an area of at least 18,000,000 acres, were originally covered with vegetation varying from semi-desert savannas of the lowest plains to coniferous forests of the high mountainous districts. Recent intensive use of the land resources of the watershed have resulted in accelerated run-off and soil erosion, destructive floods, and land deterioration. Evidences of these effects include deeply and continuously channeled alluvial valleys, deep arroyos and wide sand washes where formerly there were only shallow surface runs, gullied slopes, increasing areas or badlands, and altered courses of mountain streams. Other definite manifestations are accumulations of loose stones and sand on the ground surface, soil humps capped by vegetation and remnants of topsoil, shifting sand and sand dunes, and disappearance of luxuriant valley grasses and soils, particularly of the topsoil.

Accelerated run-off and erosion have destroyed numerous primitive irrigation works, are causing the silting up of river channels and water reservoirs, and are resulting in the waterlogging and destruction of productive farm lands. Damaging floods have apparently increased during recent years, and recreational and wildlife resources are being menaced.

The recent general decline of the watershed lands and resources began during the 1880's following the impairment of the natural vegetation cover, principally through overgrazing and also from wanton timber cutting, man-caused fires, promiscuous wagon trailing, and injudicious dry farming. The destructive floodwaters, laden with damaging silt, originate on overgrazed and damaged

range and forest lands. The more the vegetation is injured the greater the degree of accelerated soil erosion.

On only about 25 percent of the lands is there sufficient plant cover to control surface-soil erosion within normal and moderate limits, or about 35 percent accelerated soil erosion is in an advanced stage, and on 40 percent rapid land destruction is in progress. The production of forage has been reduced fully 50 percent, principally as a result of overgrazing and accelerated soil erosion.

The preservation of the land resources in this watershed depends on a protective cover of vegetation. Representative areas on which the vegetation has come back sufficiently to check accelerated soil erosion show that, through protective management, as from overgrazing, impaired vegetation cover on lands not too badly eroded will tend to renew its former protective state. The results also show that the rate of recovery will be determined largely by the quantity of topsoil left and by the precipitation water that soaks into the ground and becomes available for plants during critical periods.

"Principally because of greater annual precipitation and lower mean annual temperature, protective vegetation regenerates more rapidly on lands of the high mountainous districts than on low semiarid lands. Badly eroded spots within an area where vegetation responds quickly to protective management are soon affected by the influence of the recovering vegetation, and for this reason they heal within a comparatively short time.

"Revegetation of seriously damaged lands may be aided through the use of supplementary artificial works which serve, among other ways, in checking run-off, in preventing land break-down in drainageways, and in effecting deposition of silt in which plants may establish themselves. Supplementary works, such as levees and silt-detention dams for protecting farm lands and other properties in the main valleys, are necessary to counteract the damaging effects of accelerated run-off and erosion which result when the protective vegetation of a watershed declines; but they should never be considered an adequate substitute for the vegetation that had heretofore prevented accelerated erosion. The development and maintenance of a protective ground cover will extend the term of usefulness of such works."

Soil and water conservation in the Pacific Northwest, E. M. ROWALT (*U. S. Dept. Agr., Farmers' Bul. 1773 (1937), pp. IV+59, figs. 31*).—This deals with erosion of the soil by wind and water and with measures recommended and employed by the Soil Conservation Service for the control of erosion on the farms and ranges of the Pacific Northwest. It treats particularly of wheat lands and grazing lands.

Since soil conservation is inseparable from water conservation, certain sections deal specifically with the conservation of water for the production of crops on nonirrigated land and the conservation of water for irrigation purposes and for flood prevention. Another section deals with the control of drifting dune sands along the coastal beaches of Oregon and Washington.

Strip cropping for soil conservation, W. V. KELL and G. F. BROWN (*U. S. Dept. Agr., Farmers' Bul. 1776 (1937), pp. II+37, figs. 31*).—This reports the results of a study of strip cropping practices now under way throughout the United States and presents information including the latest developments in this field of work. It supersedes Leaflet 85 (E. S. R., 66, p. 875).

The three types of strip cropping discussed are contour strip cropping, field strip cropping, and wind strip cropping.

Public Roads, [July 1937] (*U. S. Dept. Agr., Public Roads, 18 (1937), No. 5, pp. [2]+85-100+[2], figs. 12*).—This number of this periodical contains data

on the status of Federal-aid highway projects and U. S. Works Program highway projects as of June 30, 1937, and an article entitled Laboratory, Exposure, and Simulated Service Tests of Slow-Curing Liquid Asphalts, by R. H. Lewis and W. O'B. Hillman (pp. 85-99).

Use of concrete on the farm, T. A. H. MILLER (*U. S. Dept. Agr., Farmers' Bul. 1772* (1937), pp. [2]+60, figs. 39).—This discusses the requirements of good concrete for different purposes and describes methods of building some simple concrete structures useful on the farm. It supersedes Farmers' Bulletins 1279 and 1480 (El. S. R., 55, p. 584). It was prepared with the cooperation of the Massachusetts State and North Dakota Agricultural Colleges.

Construction of farm buildings: The use of sun-dried brick, H. W. LANE (*East African Agr. Jour.*, 2 (1937), No. 5, pp. 381-383).—This is a brief presentation of information on the use of rammed and sun-dried earth for the construction of farm buildings in Kenya Colony.

Improving the farm wagon, W. P. KINTZLEY and D. P. CRAIG (*Colorado Sta. Bul. 434* (1937), pp. 7, figs. 5).—A method of low-cost improvement of the horse-drawn wagon for general farm use is briefly described, with explanation of the simple construction necessary to provide rubber tires.

Portable seed cleaning and treating equipment, C. E. SKIVER (*Indiana Sta. Circ. 230* (1937), pp. 10, figs. 4).—This equipment is described and illustrated and information given regarding its use.

The small farm type fanning mill is hardly adequate to clean the bulky field seeds properly, and receiving separators in the country elevators are regulated for the cleaning of commercial grain stocks and do not clean close enough to make the difficult separations that are necessary for the proper preparation of seed. The portable seed cleaning and treating unit which travels from farm to farm and cleans or treats the seed offers an excellent solution to the problem when properly handled. This portable equipment has the following advantages: (1) It provides the services of improved cleaning and treating equipment, such as the large type fanning mill with traveling brushes, the disk separator, and the automatic treater that most farmers cannot afford to own; (2) it is more economical to transport the equipment to the grain than it is to bring the grain in to a central point (stationary cleaner); (3) it saves labor by making all operations, such as weighing and sacking, automatic; and (4) the portable feature enables the equipment to be utilized for a long period each season, thus warranting the investment.

A seed dropper for cereal nursery rows, L. C. BURNETT (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 5, pp. 419, 420, fig. 1).—In a brief contribution from the Iowa Experiment Station a seed dropper is described and illustrated which was adapted from a chain-drive model.

Comparative tests of seed drills used in vegetable production. C. M. AGNEW and H. D. BROWN (*Ohio Veg. Growers Assoc. Proc.*, 22 (1937), pp. 5-11, fig. 1).—Investigations conducted at Ohio State University to determine the advantages and disadvantages of several mechanical features of a number of drills are briefly reported, these being preliminary to the development of more effective tools for planting and fertilizing vegetable crops. The results are presented in brief tabular form, but no conclusions are drawn.

Blueberry tillage problems and a new harrow, C. A. DOEHLERT (*New Jersey Stat. Bul. 625* (1937), pp. 12, figs. 4).—The object of the investigation covered by this report was the development of a practical cultivating tool for blueberries. In experimental work clean cultivation has been found successful as a factor in maintaining large blueberry yields, the benefits being attributed mainly to weed control. However, tillage close to the plant by

means of ordinary cultivators was found impractical after the first two years because of the low spread of the branches of the bushes, and the spread of the tops also indicated the need for a tool of light draft. Root pruning by deep cultivation checked the development of the plants, whereas shallow cultivation was found to conserve the organic matter in the soil. The practice of mounding also presented the need for a tool which is automatically adjustable to varying combinations of sloping and flat surfaces.

A new harrow was developed which meets these requirements. This development is described and illustrated.

Modern equipment for the poultry farm, A. HAY and D. F. C. VOSPER (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 7 (1937), pp. [1]+14, figs. 17*).—The essential purpose of this publication is to illustrate the use of rubber on the various types of equipment used around the modern poultry farm in England.

Dairy barn with separate milking room, C. E. WYLLIE and S. A. HINTON (*Tenn. Univ. Mimeogr. Rpt. 24 (1937), pp. 4, pls. 2*).—This is a brief description of the new dairy barn at the University of Tennessee with its essential accessories.

Sash greenhouses, J. H. BEATTIE (*U. S. Dept. Agr. Leaflet 124 (1937), pp. 8, figs. 5*).—Practical information is given on the planning and construction of sash greenhouses for use in situations where a forcing structure is needed for a brief period for starting early plants and for similar purposes.

Sash greenhouses are usually constructed of 3- by 6-ft. hotheaded sashes with a wooden framework to support them. These structures may be of various sizes, but both width and length are made to suit the 3- by 6-ft. sashes. In general, sash greenhouses are small, as the cost of large ones might easily be as much as that of standard sash-bar structures. The lean-to sash greenhouse built with a roof of sashes against the south side of a building or a tight board fence is the simplest type. Sash greenhouses may be heated by stoves, fine heaters, or steam or hot-water systems.

Illustrations are given of typical structures.

Getting the most effective results from plant refrigeration systems, L. C. THOMSEN (*Ice Cream Trade Jour., 33 (1937), No. 5, pp. 23, 24, 38*).—In a brief contribution from the Wisconsin Experiment Station, some of the differences between dairy plant refrigerating systems are pointed out and data on operation analyzed.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Kentucky Station, 1936] (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 7, 8, 9, 10-14*).—Brief general statements are included of findings (1) as to trends of tobacco prices and variations between markets of the State; (2) the more profitable farm practices as shown by farm business surveys of 37 farms in Union County, 50 Inner Bluegrass region farms, and 167 farms in southern Logan County; (3) possibilities of reducing milk cost as shown by a study of unit requirements, costs, returns, and management practices of 16 dairy herds in the Bowling Green area, 8 in the Inner Bluegrass region, and 4 in the Louisville area; (4) methods of distribution, seasonal production, and per capita consumption of milk in Lexington, and the percentages of the total milk supply sold in different forms; and (5) the factors affecting production costs and returns in 111 flocks of lambs in Owen, Grant, Washington, and Meade Counties and the Inner Bluegrass region, and in 40 herds of hogs in Union County and the Inner Bluegrass region.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul.* 187 (1937), pp. 118-124, 126, fig. 1).—An article on Generalized Land-Use Suggestions for Ohio, by J. S. Cutler, A. H. Paschall, and G. W. Conrey (pp. 118-123) includes some tentative general suggestions for land use in each of the nine districts of the State. The recommendations are based on studies made of soil conservation projects, experiences in CCC camp work areas, and on the cooperative surveys by the U. S. D. A. Agricultural Adjustment Administration and Soil Conservation Service and the station. Similarity of soils, topography, and erosion were the criteria used in determining the district boundaries. A table by J. I. Falconer shows by years 1929-36, inclusive, the estimated number of tons of different commercial feeds reaching the retail trade in Ohio. The table of index numbers of production, prices, and income, by Falconer (E. S. R., 77, p. 551) is brought down through April 1937.

Current Farm Economics, [August 1937] (*Oklahoma Sta., Cur. Farm Econ.*, 10 (1937), No. 4, pp. 65-85, figs. 4).—Included are the usual tables of index numbers and review of the agricultural situation and articles on Some Economic Aspects of the Price Paid to Producers for Butterfat in Oklahoma, 1926 to 1935, Inclusive, by A. W. Jacob (pp. 68-71); Quality, Yield, and Production of Cotton in Oklahoma, 1936, by K. C. Davis (pp. 71-74); and The Land Tenure Problem in Oklahoma, by P. Nelson (pp. 74-83).

[Investigations in agricultural economics by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1936], pp. 2-9).—Some findings not previously noted in studies are included as follows: (1) Number of hens housed in the fall of 1935 as compared with 1934 and the percentage of eggs marketed by different methods in three areas of Rhode Island; (2) average labor incomes of 45 poultry farms in 1935; (3) the receipts of canned milk by rail in Rhode Island in 1933, 1934, and 1935, average daily receipts and sales of fluid milk in the Newport market April 1934 to February 1936, inclusive, and the total receipts in Rhode Island and the percentage of such receipts sold as fluid milk July 1934 to January 1936, inclusive; and (4) the changes in prices of Class I milk, f. o. b. the distributor's plant in Providence, and in the price of dairy rations January 1922 to December 1935, inclusive.

Economic studies of vegetable farming in New York.—I, Market-garden farms with greenhouses, Rochester area, G. A. M. BAPTIST and E. G. MISNER ([*New York*] *Cornell Sta. Bul.* 671 (1937), pp. 51).—Data obtained in a farm management study covering the years ended March 31, 1933, 1934, and 1935, are analyzed. Seventy-two farms were included in 1933 and 50 each in 1934 and 1935. Tables cover capital invested, receipts, expenditures, operator's labor income, outside and greenhouse crops, sales of crops, amount of livestock, use of fertilizers and manure, prices received, etc. The relations between labor income and size of business, diversity of business, labor efficiency, and efficiency in the use of capital are discussed. "As an average for the 3 yr., each of the following factors contributed to the labor income the following amounts: (1) Capital employed, no change in labor income per increase of \$1,000 in capital; (2) receipts per \$100 of capital, \$91 in labor income for each increase of \$100 in receipts per \$100 capital; (3) receipts per man, \$150 in labor income per increase of \$100 in the receipts per man; [and] (4) greenhouse receipts per 100 sq. ft. of greenhouse area, \$76 in labor income per increase of \$1 in greenhouse receipts per 100 sq. ft. of greenhouse area."

A farm-management-efficiency program for New York market-garden farms is included.

Growers' contracts for sweet corn: An analysis of different types of canner contracts and the relation of maturity to yields and quality, W. A.

HUELSEN (*Illinois Sta. Circ. 472* (1937), pp. 16).—Using the experimental data previously noted (E. S. R., 77, p. 626), the progressive changes in yields of sweet corn as maturity advances and the bearing of these changes on methods of drawing contracts are discussed.

Farm management for fruit growers, T. H. LAMONT and P. S. WILLIAMSON (*N. Y. State Col. Agr., Cornell Ext. Bul. 355* (1936), pp. 90, figs. 36).—This bulletin is devoted chiefly to apple orchard management. Costs of spraying, dusting, cultivating, fertilizing, pruning, etc.; the relation of these factors, age of trees, trees per acre, etc., to yield, and of soil, yields, size of farm, labor efficiency, etc., to costs and returns; and the yields, prices, and returns of important varieties are discussed.

Cost of producing apples in Berrien County, Michigan, 1935, K. T. WRIGHT and W. R. O'BRIEN (*Michigan Sta. Spec. Bul. 286* (1937), pp. 35, figs. 6).—Records were obtained from 80 cooperators covering hours of labor spent in apple orchards, amount and cost of all material used, investment in special equipment, numbers of bearing and nonbearing trees, production and value of apples, and conditions and practices followed in the orchard. An analysis is made showing by items the costs of production, marketing, and overhead, and the income, and also of the effects of different factors on costs and returns.

Production costs per acre averaged \$36.13, harvesting and marketing costs \$37.37, and overhead costs \$31.13. The orchards averaged 12.5 acres and the yield 184 bu. per acre. The returns, including appreciation of trees, averaged \$106.19. The average profit was \$1.56 per acre, or 0.8 ct. per bushel. The 15 most profitable orchards showed a profit of \$43.32 per acre, while the 15 least profitable orchards showed a loss of \$36.83 per acre. A yield of approximately 200 bu. per acre was necessary to pay costs of production in 1935 if no credit was allowed for appreciation of trees. Orchards with from 35 to 40 trees per acre gave the highest returns. Costs per bushel averaged lowest in orchards of from 10 to 20 acres.

An economic study of grape farms in Schuyler and Yates Counties, crop year 1935, E. G. MRSNER ([*New York*] *Cornell Sta. Bul. 670* (1937), pp. 27, fig. 1).—Records were obtained for the year ended March 31, 1936, for 100 farms with vineyards in Yates County and 81 farms with and 19 farms without vineyards in Schuyler County. An analysis is made to show the capital invested, receipts, expenses, financial returns, the effects of size of business, diversity of enterprises, rates of production, labor efficiency, and efficiency in the use of capital upon operator's labor income. A farm-management-efficiency system for grape farms in the area is included.

Economic aspects of lamb feeding in Michigan, K. T. WRIGHT (*Michigan Sta. Spec. Bul. 284* (1937), pp. 24, figs. 5).—An analysis is given of 164 lamb feeding cost records covering approximately 130,500 lambs fed during the years 1930-35, inclusive. Tables are included and discussed showing (1) the costs and returns by years and the averages for the period, and (2) the effects on costs and returns of date of purchase, number, source, and initial weight of lambs, length of feeding season, method of feeding, feeding efficiency, death loss, daily gain, and margin between the purchase and selling prices of lambs. The place of lamb feeding on Michigan farms is discussed. Using the results of the analysis, a chart is designed for calculating the feed cost per lamb with concentrates and hay at different prices and one for showing the margins necessary to pay all expenses with different lamb purchase prices and feed costs per fat lamb.

The total cost of fat lambs averaged \$6.51 each, of which the cost of feeder lambs made up 63 and feed 31 percent. The average cost of fattening a lamb was \$2.44, of which feed constituted 82, use of barn and equipment 6, and labor 5 percent. The average net returns per \$1 worth of feed fed ranged from a loss of 5 ct. in 1934-35 to a value of \$1.79 in 1933-34, averaging \$1.40 for the period. The average feeding period was 110 days, the average gain 26 lb., and the average net return per lamb finished 80 ct. An average of 141 lb. of concentrates and 125 lb. of roughage were fed per lamb.

Feeding ability of the farmer, margin between purchase and sale price of lambs, rate of daily gain, and death loss were the factors of particular importance affecting costs and returns.

Dairy-farm management, L. C. CUNNINGHAM (*N. Y. State Col. Agr., Cornell Ext. Bul. 364* (1937), pp. 36, figs. 10).—This study is based on 2,737 labor income survey records for grade B dairy farms during 1925-34, inclusive. Analysis is made of the amounts and changes in labor income and the effects of size of business, labor and capital efficiency, rate of milk production, egg production, crop yields, and supplementary enterprises on labor incomes.

The average labor income per farm decreased from \$715 for the first 5 yr. to \$55 for the second 5 yr. In general, the larger the farm business the larger the income, but size had but little effect in years of low prices. Milk production per cow was the most important factor affecting income. Fairly uniform production throughout the year paid better than summer dairying. High crop yields, moderate specialization in dairying, full use of capital, and labor also increased income.

Studies in Vermont dairy farming.—X, Feed as a cost of milk production, G. E. BOND and J. A. HITCHCOCK (*Vermont Sta. Bul. 421* (1937), pp. 38, figs. 5).—In continuing the series previously noted (*E. S. R.*, 75, p. 367), an analysis is made of 452 dairy enterprise records for the year ended March 31, 1933, obtained in the Champlain Valley for the purpose of determining the factors affecting winter milk production costs.

Grain fed in the winter averaged 52 lb. per cow per day, being 1 lb. for each 2.6 lb. of milk produced. As the amount of grain fed per day increased from about 2 lb. to approximately 6 lb. the average daily milk production rose from 10 to 15 lb. and the net cost of milk production declined. Herds fed over 7 lb. of grain per day per cow averaged little more than 15 lb. of milk per cow and the net cost of milk production was higher. Response to changes in the amount of grain fed and the point at which unit costs of milk were lowest varied somewhat with the season of freshening. Production per cow was lower and the net cost of milk higher on the farms where most of the grain was home-grown than on those where most, or all, of the grain was purchased. Milk yields tended to be higher as the digestible protein content of the grain ration was higher. Silage cost more per hundredweight of digestible nutrients than hay. Production increased as the silage feeding rate rose but not sufficiently rapidly to keep pace with the higher cost of the ration. Production per cow did not vary with differences in rates at which hay was fed, and milk was produced at a lower cost when relatively small amounts of hay were fed.

A survey of research in forest economics (Social Sci. Res. Council Bul. 24 (1936), pp. VII+52).—A report prepared under the direction of The Committee on Social and Economic Research in Agriculture.

Agriculture on the Huntley project, P. L. SLAGSVOLD (*Montana Sta. Bul. 342* (1937), pp. 20, figs. 17).—The soils, topography, climate, water supply, etc., of the project are described. Data are presented in tables and charts and

discussed in regard to size of farms, land tenure, use of lands, acreages and yields of crops, animal units per farm, tax delinquency, value of farm and improvements, sources of farm income, etc.

Systems of farming and possible alternatives in Nebraska, L. F. GAREY (*Nebraska Sta. Bul. 309 (1937), pp. 50, figs. 27*).—This bulletin analyzes in detail the type-of-farming areas of the State previously described (El. S. R., 75, p. 709) and presents methods useful in adjusting production in changing economic conditions. In general, there are included and discussed for each area tables and charts showing the percentages of crop land in different crops and the numbers of livestock units of different kinds by years 1910-34, inclusive; the organization of the most typical farms of different sizes; the cropping system and an alternative cropping system for the most common size farm; and the disposal of feed—farm-grown and purchased—to livestock under the original cropping system. The returns under the original cropping system and one or more alternative plans are discussed.

The relation of size of farm to tax, labor, improvement, and other farm expenses in Nebraska, L. F. GAREY and R. W. HECHT (*Nebraska Sta. Bul. 308 (1937), pp. 24, figs. 6*).—This bulletin is based on information covering the period 1914-34, obtained through farm management surveys and farm account books. Records for 2,097 owner-operated farms, 1,881 part-owner-operated farms, and 2,376 tenant-operated farms were obtained. Tables and charts with discussions show the relation of size of farms, and in some cases cash income, to expenditures for horses and machinery, livestock, feed, grain, and supplies, crop expenses, labor, taxes, and improvements, and also total expenses and fixed and variable expenses. The findings are summarized as follows:

The amount of farm expense varied with the size of business, as indicated by acres per farm and with the amount of cash income from the farm. In the same type of production, large farms had more expense than small farms, although the expenses increased at a slower rate. In general, taxes increased with the size of farm, but the tax per acre decreased. In general, variable expenses resulted in more direct income than fixed expenses. Farmers used their old machinery and improvements when times were bad rather than increase their indebtedness to maintain their capital. When good times returned, the depleted capital was replaced with new and more modern machinery and improvements. The amount of income left after cash expenses had been paid is indicative of the amount left for living and capital obligations. Large farms had not only more total cash income but more for living and capital obligations after the variable expenses were deducted.

An economic study of land utilization in Genesee County, New York, J. N. EFFERSON ([*New York*] *Cornell Sta. Bul. 668 (1937), pp. 42, figs. 19, map 1*).—This bulletin is the seventh in the series previously noted (El. S. R., 76, p. 552). The analysis and discussion follow the same general outline as those in the previous bulletins.

A study of land utilization in Washington and Kent Counties, Rhode Island, B. H. GILBERT (*Rhode Island Sta. Bul. 261 (1937), pp. 32, figs. 6*).—Land cover surveys were made during the years 1932-35, inclusive. Tables and charts show by towns (1) the acreages in different kinds of timber, pasture, hay, different cereals, vegetables, fruits, waste, marsh, etc.; (2) the soil types and estimated acreages of different cover types on the different soils; and (3) estimated acreages of land classified according to suitability for certain uses.

The grazing of maple sugar orchards, J. A. HITCHCOCK (*Vermont Sta. Bul. 414 (1937), pp. 14, figs. 2*).—Data were obtained for 96 farms in northeastern Vermont with sugar orchards regarding land use, livestock pastured, forest

products—sirup, sugar wood, and lumber—and fencing costs, and also regarding sirup production on 125 other sugar orchards in the State.

Sugar orchards occupied one-third of the woodland area on the 96 farms. During the period 1931-36 the value of wood and lumber harvested averaged \$147 per farm (\$2.05 per acre of woodland) and that of sirup \$260 (\$11 per acre of sugar orchard). Farm operators estimated it would require an average of 142 rods of fencing per farm and a cost of \$247 per acre to exclude livestock from their sugar orchards. "Examination of typical orchards indicated that in a very high percentage of them maple reproduction has been destroyed by grazing and that as the present maples mature and are harvested there will be none on the same sites to take their place."

A study of the operation of the 1936 soil conservation program in Vermont, J. A. HITCHCOCK (*Vermont Sta. Bul. 413 (1937), pp. 14, fig. 1*).—This study was made to identify any factors or characteristics associated or not associated with participation in the 1936 soil conservation program and to examine the effects of the program on the farm practices of the participants. Records of acreages and yields of crops in 1935, of crops, pasture and woodland acreages and numbers of livestock on hand in 1936, and fertilizer applications in 1935 and 1936 were secured for 988 farms in 9 townships scattered throughout the State.

The data indicated that participation in the 1936 program was more general among operators of large farms, among operators handling their farms intensively, and among farm bureau members. Farmers who filled out conservation program work sheets applied 43 percent more commercial fertilizer in 1936 than in 1935, as compared with 21 percent for nonparticipants. The program was also responsible for an appreciable increase in the acreage stocked down.

Financial results of two years' farm operations in New Brunswick I. S. McARTHUR (*Sci. Agr., 17 (1936), No. 3, pp. 163-165*).—Tables based on a previous study and records obtained in 1936 for 70 farms in Carleton and Victoria Counties show for 1935 and 1936 the utilization of lands, receipts, expenses, farm income, operator's income, etc.

A study of land utilization, farm production, and rural living [in Antigonish County, Nova Scotia], W. V. LONGLEY and W. F. CROWN (*Nova Scotia Dept. Agr. Bul. 118 (1936), pp. 112, pls. 6, figs. 5*).—In this study, made in 1935, the general economic conditions were studied and farm survey records obtained from 163 farms in 10 districts of the county. The types of farming, utilization of land, livestock enterprises, farm income and expense, factors affecting farm living conditions, population and production trends, tax delinquency, schools, communications and services, community organizations, markets and marketing, etc., are discussed.

Land utilization in southwest central Saskatchewan, C. C. SPENCE (*Sci. Agr., 17 (1936), No. 3, pp. 157-161*).—Using data from economic surveys made in 1935 and covering 836 farms in 7 rural communities, tables are included and discussed showing the use of land, topography and types of soils of all lands and cropped lands, changes in the use of lands since 1916, and yields, farm prices, and value per acre by years, 1923-34, of fall rye and wheat.

A graphic summary of the value of farm property, B. R. STAUBER and M. M. REGAN (*U. S. Dept. Agr., Misc. Pub. 263 (1937), pp. 11-20, figs. 24*).—This publication, which is based largely on the census of 1930 and 1935, continues the series previously noted (*E. S. R., 77, p. 714*).

Value of farm land and buildings for North Dakota by counties, 1910-1930, and for United States, 1850-1930; value of farm land alone for

North Dakota by counties, 1920-1930, C. E. MILLER, C. BJORNSON, and W. BROWN (*N. Dak. Agr. Col.*, 1935, pp. [18], figs. 9).—The data were obtained chiefly from the Federal census reports and are presented in tables, maps, and charts. Data for North Dakota are also included on the assessed values as shown by reports of the State tax commissioner.

Semi-annual index of farm real estate values in Ohio, July 1 to December 31, 1936, H. R. MOORE (*Ohio State Univ., Dept. Rural Econ. Mimeo.* *Bul.* 98 (1937), pp. 6).—This is a continuation of the series (*E. S. R.*, 76, p. 260).

Assessed values and wheat yields, Oneida County, Idaho, P. A. EKE (*Idaho Sta. Bul.* 221 (1937), pp. 10-12, fig. 1).—A table shows the assessed valuations of irrigated and dry farm land, the lands being grouped on the basis of wheat yields and whether or not taxes were delinquent in January 1934.

Improved roads and land values, C. L. STEWART (*Ill. Engin. Expt. Sta. Circ.* 27 (1936), pp. 47-64).—A brief summation is made by European countries and States of the United States of the findings in studies of the effects of improved roads on land values.

Farm tenancy (*Washington: Govt.*, 1937, pp. VII+28; also in *Rural Amer.*, 15 (1937), No. 3, pp. 3-15).—This is a message of President Roosevelt, transmitting to the Congress findings and recommendations of the Special Committee on Farm Tenancy and the National Resources Committee.

Protection of agricultural production and of the export of agricultural products in some South American countries: Results of this policy, E. MARTINEZ (*Internat. Rev. Agr. [Roma]*, 27 (1936), No. 12, pp. 382E-401E).—The protection policy and its results in Argentina, Brazil, and Uruguay are discussed.

Sugar: A case study of Government control, J. E. DALTON (*New York: Macmillan Co.*, 1937, pp. X+311).—The subject is dealt with in chapters on the point of view; the industry involved; the historical background; the world sugar depression; the national sugar depression; the stabilization agreement—industry's plan; the sugar act—Government's plan; the plan in action—rationalization of marketing; the plan in action—the adjustment of production; the beet sugar industry; the domestic cane sugar industry—Louisiana and Florida; Hawaii, Puerto Rico, the Philippine Islands—the background; the insular areas under the Sugar Act; Cuba; the refiners; the consumer; a brief review; and some wider problems.

Three years of the Agricultural Adjustment Administration, E. G. NOURSE, J. S. DAVIS, and J. D. BLACK (*Washington, D. C.: Brookings Inst.*, 1937, pp. XIV+600, [figs. 22]).—This is the final volume of the series previously noted (*E. S. R.*, 75, p. 413).

The conclusions of the authors "take the form of interpretations of the actual play of economic forces under the new institutional situations, definition of issues, and setting up of alternatives rather than condemnation or recommendation of the AAA in its entirety or even of particular ones of its varied procedures under all circumstances." The chapters deal with agricultural adjustment as national policy; the adjustment act and supplementary laws; administrative set-up; summary view of AAA programs; experience in controlling production; commodity loans and related proposals; commodity purchase and diversion operations; marketing agreements, licenses, and Secretary's orders; administrative problems; effects on farmers' returns; distribution of benefits and burdens among farmers; effects upon farm management and the organization of agriculture; effects upon consumers, the agricultural trades, and taxpayers; contributions to general economic recovery; and AAA philosophy in the light of experience. Supplementary statements by

J. S. Davis and J. D. Black are given. Appendixes include a description, by H. B. Rowe, of the specific analyses used in ascertaining the benefits and burdens of adjustment programs; addresses by the Secretary of Agriculture, H. A. Wallace, on agricultural security, and by H. R. Tolley on soil conservation and agricultural adjustment; and statistical tables.

The Agricultural Adjustment Act and the reports of the Brookings Institution, F. B. GAEVER and H. TRILOGAN (*Quart. Jour. Econ.*, 50 (1936), No. 4, pp. 594-621).—A review is made of the series of reports of the Brookings Institution previously noted (E. S. R., 75, p. 413) on the dairy industry, wheat, livestock, cotton, tobacco, and marketing agreements under the Agricultural Adjustment Administration.

Who paid the processing taxes—the first time? W. F. FEEGER (*South. Econ. Jour.*, 3 (1937), No. 3, pp. 255-269, figs. 2).—The author discusses the processing taxes and concludes that "in a realistic sense, and considering the secondary institutional factors in the total situation, nobody paid the processing taxes because of the reconstructive nature of the forces set in motion by the agricultural program. It is not suggested that such an answer disposes of the question of the immediate incidence of the processing taxes. Obviously, at a given time and under given conditions a tax actually collected from a processor comes out of someone's pocket."

Farm cash income in Texas, 1927-1936.—Preliminary report, F. A. BURCHEL (*Austin: Tex. Univ., Bur. Business Res.*, 1936, pp. [6]+59, [pls. 9, fig. 1]).—This includes and discusses tables, charts, and maps showing the crop reporting districts of the State, utilization of agricultural lands, monthly prices of farm products, sources of agricultural income (1929), trends and seasonal variation in cash farm income, and the monthly indexes of such income.

Prices in recession and recovery, F. C. MILLS (*New York: Natl. Bur. Econ. Res., Inc.*, 1936, pp. XV+581, figs. 16).—This survey of recent changes presents "a monographic treatment of certain aspects of recession and recovery in the United States during the last 7 yr. Various measurements constructed by the National Bureau in connection with its continuing work are of some current interest to economists and others who follow economic movements. Discussion of these and related materials falls easily into half a dozen divisions, dealing with the background of the price recession of 1929, its world setting, and the fortunes of primary producers, fabricators, and consumers during the disturbed years from 1929 to 1936. Although no rounded survey of the situation as a whole is made, something of unity in the price history of these various groups is found in tracing the incidence of productivity changes in manufacturing industries and their relation to changing costs and prices. This topic is developed in the final chapter."

The material is presented in chapters on general aspects of recent price movements, the prerecession situation, price movements and related economic changes during recession and depression, the world price structure in recession and recovery, price changes and the fortunes of primary producers in recovery, manufacturing industries in recovery, capital equipment and construction in recovery, consumers' goods in recovery, and the price system, increasing productivity, and recent economic changes.

Prices of North Dakota farm products, 1929-1935, C. E. MILLEL and C. BJORNSEN (*N. Dak. Agr. Col.*, 1935, pp. [12]).—The tables of monthly prices previously noted (E. S. R., 62, p. 783) are brought down through June 1935.

The farmer looks ahead: Four yardsticks for measuring future farm production (*U. S. Dept. Agr., Farmers' Bul.* 1774 (1937), pp. 16, figs. 7).—The

size of the agricultural production, 1928-32, and the amount that should be produced in the future are discussed. The proper future production is measured by the requirements of domestic consumption, foreign demand, the need for soil conservation, and the production that will give the greatest farm income.

Grade, staple length, and tenderability of cotton in the United States, 1928-29 to 1935-36 (*U. S. Dept. Agr., Statis. Bul. 60 (1937), pp. 60, figs. 10*).—This bulletin continues the series previously noted (*E. S. R., 77, p. 719*). Detailed tables are included for the 1935 crop year and more general tables for preceding crops.

Cotton bale enquiry (*Internatl. Cotton Bul., 15 (1937), No. 58, pp. 213-245*).—Analysis is made of the answers to an inquiry sent out by the International Federation of Master Cotton Spinners' and Manufacturers' Associations regarding weights, densities, measurements, details of covering and banding, etc. Tables present data by countries as to measurements, weights, and density of cotton bales; types of and weights and yardage per bale of covering; numbers, dimensions, weight, and method of fastening bands, ties, and wires; and types of gins, place of pressing bales, range of lengths of staple, export taxes, and volume of exports.

Fruits and vegetables: Agricultural income inquiry (*Washington: Govt., 1937, pp. V+16*).—This interim report of the Federal Trade Commission includes its conclusions and recommendations as to terminal market inspection, loss and damage claims, unfair rejections, failure properly to account to shippers, misbranding, terminal cartage, terminal facilities, and cooperative marketing. Appendixes include Public Resolutions 61, 86, and 112 of the Seventy-fourth Congress.

Market outlets for Minnesota fruits, J. D. WINTER, W. C. WAITE, and W. H. ALDERMAN (*Minnesota Sta. Bul. 332 (1937), pp. 36, figs. 8*).—The findings in a preliminary study of the marketing problems of Minnesota-grown fruits, with special reference to their utilization in commercial manufacture, are presented. The commercial production of raspberries and strawberries in Minnesota in 1935 and 1936, the methods of distribution, the volume used in the manufacture of jam and preserves and ice cream, as crushed fruit for soda fountain trade, in the baking industry, and for commercial canning, are discussed. The changes in variety or improvement in quality necessary to increase the use of strawberries and raspberries for commercial manufacture, the use of Minnesota apples, plums, and grapes for commercial manufacture, and the value of Minnesota apples for commercial baking are also discussed. The established grades and legal requirements for berries are described. Some of the findings were as follows:

Almost the entire crop of Minnesota-grown raspberries and strawberries is sold as fresh fruit for table use and home canning. Less than 2 percent of the sum expended by commercial factories in Minnesota for raspberries and strawberries is spent for Minnesota-grown berries. There is a wide market for Minnesota-grown raspberries in the preserving industry at prevailing prices for preserving berries. There is opportunity for the development of a market for Minnesota strawberries in the ice cream business, but no sizable market for raspberries in that industry. Factory tests of the Dolgo crab, Hednepen plum, and Sapa cherry-plum showed that they are very satisfactory for commercial preserves and jelly. Most of the 14 varieties of apples tested were satisfactory for the commercial pie industry and one, Minnesota No. 790, was entirely satisfactory for the baked apple trade.

Marketing apples in the Champlain Valley, G. P. SCOVILLE ([*New York Cornell Sta. Bul.* 669 (1937), pp. 41, figs. 11).—The varieties of apples grown, grades sold and prices received, markets, seasons, and methods of marketing, storage, transportation, packing, and commission costs are described and discussed. The more detailed data used covered the years 1933-35, inclusive. Some comparable data are also included for Ulster and Niagara Counties and the Hudson Valley, and some data as to New York City prices. The effects of deflation in selling prices of apples, costs of marketing, and returns to growers are briefly discussed.

Frozen-pack fruit markets, H. CARLTON (*Tennessee Sta. Bul.* 161 (1937), pp. 72, figs. 10).—This study deals principally with strawberries and was undertaken primarily for the purpose of locating additional markets for Tennessee strawberries. Other frozen fruits and certain vegetables are also included because of their competition with strawberries or as desirable products for Tennessee growers and processors. The field work was done between June 15 and December 15, 1935, and the reports and estimates are based on a combination of the 1934 and 1935 packs.

"Consumers, processors, cold storage operators, brokers, jobbers, wholesalers, and retailers in the large consuming centers were interviewed, and trade publications and associations and individuals familiar with the food industry were consulted for general information. Agricultural experiment stations and State and Federal departments were visited for experimental, processing, and statistical information."

The bulletin covers, among other things, the production and consumption of frozen-pack fruits in the United States and Canada; the areas of production; important markets; varieties of fruit used; the use of frozen-pack fruits in the preserve, ice cream, and pie industries, in institutions, and for home consumption; types of containers used; methods and cost of transportation; cost of packing, storing, etc.; selling prices: etc.

The methods of cold-packing strawberries and varieties and types of berries found most satisfactory are discussed. Similar brief descriptions are included for other fruits, especially peaches and cherries. The increasing demand for frozen fruits and vegetables for institutional and retail trade is also discussed. A chart shows the normal packing periods for different fruits and vegetables in the Pacific Northwest States and Tennessee.

Country milk-receiving and cooling stations, C. E. CLEMENT (*U. S. Dept. Agr. Circ.* 432 (1937), pp. 60, figs. 32).—This circular, which applies chiefly to stations from which all milk is shipped as market milk, presents information as to the construction, arrangement, operation, volume requirements for economical operation, labor requirements, methods of transportation, etc., of country receiving and cooling stations, and the relative advantages and economies of such stations as compared with direct shipment. Plans are included for the construction of plants of various capacities.

Co-operation and the new agricultural policy (London: P. S. King & Son, 1935, pp. VIII+136).—This volume, prepared by the Horace Plunkett Foundation, describes the historical and legal background of cooperation in England, Scotland, and Northern Ireland in different agricultural commodities; includes a classification of agricultural planning in 1935 and an assessment of results; and discusses the new British policy and the organization of agricultural marketing in overseas countries resulting from the altered British market or the impulse to meet falling agricultural prices by organizational or restrictive measures.

Agricultural co-operation in Fascist Italy, with a full account of the general organization of co-operation, F. CORRA (London: P. S. King & Son,

1935, pp. XVII+148).—The subject is dealt with in chapters on the genesis of the present organization, legislation governing cooperation, the Fascist National Organism of Cooperation, agricultural labor and cultivation societies, collective purchase and marketing societies, processing societies, rural or agricultural credit societies, cattle insurance societies, national federations, the Italian Federation of Agricultural Consortia, and propaganda and education, and a chapter summarizing the author's findings as to how Italian cooperation stands in the light of orthodox cooperative principles and of present-day practice and economic requirements.

Consumers' cooperation throughout the world in 1935 (*U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev., 44 (1937), No. 1, pp. 79-95*).—Tables are included and discussed showing by countries the number and membership of retail, wholesale, credit, productive and labor, housing and construction, agricultural, and miscellaneous associations.

Agricultural statistics, 1937 (*U. S. Dept. Agr., 1937, pp. [1]+486*).—This volume, prepared under the direction of J. A. Becker et al., the Yearbook statistical committee, continues the series previously noted (*E. S. R., 76, p. 124*). It includes statistics of different grains, cotton, sugar, tobacco, different fruits and vegetables, miscellaneous crops, beef cattle, hogs, sheep, horses, mules, dairy and poultry, foreign trade in agricultural products, farm business and related subjects, and miscellaneous subjects such as forestry, weather, roads, etc.

The first world agricultural census (1930), A. BRIZI (*Roma: Internatl. Inst. Agr., 1936, prov. ed., pp. [VII]+229*).—This is "a methodological study of the questions contained in the forms adopted for the purposes of the census in the various countries." General information is given as to the countries taking part in the census and the procedure in each. The questions proposed in the standard form, in the appendix to and supplementary to that form, and questions not included in the standard form but occurring in the schedules of certain countries are discussed. The standard form is given in the appendix.

RURAL SOCIOLOGY

Recent changes in the social and economic status of farm families in North Carolina, C. H. HAMILTON (*North Carolina Sta. Bul. 309 (1937), pp. 180, figs. 59*).—The depression is credited with the displacement, unemployment, and impoverishment of thousands of farm families; a back-to-the-(poorest)-land movement; an increase in farm tenancy in western North Carolina, a region of traditional home ownership; a repression of the natural ambitions and functions of the rural youth on farms; a curtailment in normal governmental and other social institutions; and the loss of faith in traditional capitalistic, social, and economic institutions.

This study shows that "the AAA was definitely not to blame for increased displacement of tenants and croppers. Except in a few areas, the curtailment in cotton and tobacco acreage was accomplished not by eliminating farmers but by reducing the average number of acres per farmer."

There is, even in normal times, a constant movement of farmers up and down the agricultural ladder. The rural birth rate fell very little if any at all during the depression, and there is some indication that it has turned upward or at least leveled out during the years 1933, 1934, and 1935. There is some evidence that farm tenancy is, over a long period of time, increasing rather than declining. Another long-time trend is the accelerated drift of Negroes out of agriculture during the past 5 yr.

Promising signs are rural electrification, better rural schools, lower birth rates, less infant mortality, and better rural health organization. "A new agricultural program and the resettlement program also holds great promise for saving the land and the people."

Rural population and community studies (*Kentucky Sta. Rpt. 1936, pt. 1, pp. 9, 10*).—In 12 school districts in the Eden Shale area of Anderson County factors in the migration of young persons from this county were studied.

The relief problem in Montana: A study of the change in the character of the relief population, C. F. KRAENZEL and R. B. MCINTOSH (*Montana Sta. Bul. 343 (1937), pp. 64, figs. 12*).—This study includes the extent and trend of relief in Montana, characteristics of the relief population, family composition of relief households, age and sex distribution of relief compared with the non-relief population, and the occupational history of heads of relief households.

A study of the characteristics and occupations of 1,100 part-time Rhode Island farmers (*Rhode Island Sta. Rpt. [1936], pp. 35-38*).—Data are included on the extent to which rural living and the production of farm produce for home consumption and for sale are combined with occupation in nonagricultural enterprises and on the composition and characteristics of the families studied, with some general facts relative to their diets and households.

Recreation and the use of land in Washington County, W. R. GORDON and B. E. GILBERT (*Rhode Island Sta. Bul. 258 (1937), pp. 83, figs. 27*).—This is an inventory of the real estate used for recreational purposes. The field work was done in 1934. Measured in extent of land use, agriculture has been declining in the county since 1880, with either reversion to woodland or development for country estates, suburban homes, or summer residences. The development of industry, the concentration of population in the Northeastern States, and improved transportation combined with the natural advantages of location, climate, seashore, inland ponds, and woodland have all had their influence in extending the use of land for recreational purposes. Of the total land area in the county, 10.46 percent is now in recreational use. Considering the eight types of recreational use, summer residences command 65.4 percent of all recreational land, with recreational clubs 11.3 percent and public parks 10.9 percent. Privately-owned recreational land constitutes 88.34 percent of the total recreational acreage. On the basis of assessed valuation, this privately-owned recreational land represents 37.25 percent of the county's total, while the average per acre figure indicates that it ranks with the most valuable land in the county.

The total gross valuation of all recreational real estate amounted to \$17,010,351, or approximately 35.39 percent of the county total. Summer residence property accounts for 90.92 percent of its total valuation, with summer hotels the next class. "The recreation industry is of notable importance measured solely on the basis of its use of land, and there is justification for the belief that such use is destined to increase in the area studied."

AGRICULTURAL AND HOME ECONOMICS EDUCATION

[Proceedings of the fiftieth annual convention of the Association of Land-Grant Colleges and Universities], edited by W. L. SLATE (*Assoc. Land-Grant Colls. and Univs. Proc., 50 (1936), pp. 376*).—This is the report of the convention held at Houston, Tex., November 16-18, 1936, and previously discussed (*E. S. R., 76, pp. 1, 144, 145*). Included are the papers and discussions thereon presented in the general sessions of the Association, in the joint sessions of the section on agriculture and the subsections on resident teaching, experiment station work, and extension work, and in the sections on engineering and home economics. Also included are the minutes of the executive body of the Associa-

tion, the minutes of the conference of deans of graduate schools, reports of committees, the constitution of the Association, and lists of officers and committees for the succeeding year.

History of the Agricultural and Mechanical College of Texas, C. OUSLEY (*Tex. Agr. Col. Bul.*, 4 ser., 6 (1935), No. 8, pp. [3]+172, figs. 4).—The history of the administration and teaching, experiment station, and extension work of the college are discussed.

Statement of policies for the administration of vocational education (*U. S. Dept. Int., Off. Ed., Vocat. Ed. Bul.* 1 [3.] rev. ed. (1937), pp. IX+137).—"Part 1 of this publication [E. S. R., 38, p. 597] describes briefly the administrative relationship established between the States and the Federal Government under the vocational education acts for the promotion and development of the cooperative program of vocational education in the States; and also includes in outline form the legal requirements imposed by the Smith-Hughes and George-Deen Acts. Part 2 comprises general policies or standards adopted by the Office of Education. Part 3 discusses specific questions of administration of the vocational education program raised from time to time in conferences with representatives of State boards for vocational education or which arise in the day-to-day administration of the act, and explains the rulings adopted on these questions."

Appendixes include (1) the texts of the vocational educational act approved February 23, 1917 (Smith-Hughes Act), the vocational rehabilitation act approved June 2, 1920, the vocational education act approved June 8, 1936 (George-Deen Act), amendments to these acts, and acts providing for vocational education and rehabilitation in Hawaii, the District of Columbia, and Puerto Rico; (2) tables showing the grants and allotments available under the several acts; and (3) a topical outline for State plans for a 5-yr. period, July 1, 1937-June 30, 1942.

Southern field-crop enterprises (*Chicago: J. B. Lippincott Co.*, 1937, 2. ed., rev., pp. XXVII+574, figs. 232).—The tabular and other data, reference lists, etc., in this textbook (E. S. R., 61, p. 290) have been revised. New sections on soils and other plant relationships, conservation and improvement of soils, land drainage, and prevention of soil erosion—terracing—are included. The sections were written by the following authors, with the assistance of subject matter and vocational education specialists: Cotton enterprise, by E. R. Alexander; corn, by D. M. Clements; small grain, by E. G. Matthew; sorghum, by E. B. Nelms; grass and clover, by Z. M. Smith; alfalfa, by R. I. Throckmorton; peanut, soybean and cowpea, and other annual legumes, by W. S. Newman; Irish potato, by J. K. Coggin; sweetpotato, by W. H. Garrison; tobacco, by F. G. Burd; rice and sugarcane, by J. G. Lee, Jr.; and truck crops, by E. W. Garriss.

The feeding of crops and stock, I-III, A. D. HALL (*London: John Murray*, 1937, 2. ed., [rev.], pts. 1, pp. IX+120, figs. 18; 2, pp. IX+122, figs. 9; 3, pp. XI+108, figs. 5).—This introduction to the science of the nutrition of plants and animals is a revision and enlargement of the book previously noted (E. S. R., 25, p. 626), the three parts being published separately. Part 1, *The Plant*, includes chapters on what the plant is made of, the work of the leaf, the work of the roots, changes of composition within the plant, and reproduction. Part 2, *Soils and Fertilizers*, includes chapters on the origin and nature of soils, cultivation and the movements of soil water, the living organisms of the soil, fertilizers and manures, and the improvement of soils. Part 3, *The Nutrition of Animals and Man*, includes chapters on the animal, energy required for maintenance, the productive ration, feeding for production, the composition of feeding stuffs, food accessories, rations for livestock, valuation, and human dietaries.

Elements of statistics, H. T. DAVIS and W. F. C. NELSON (*Bloomington, Ind.: Principia Press, Inc., 1937, 2. ed., rev., pp. XII+434, figs. 510*).—This text is designed for a 6 to 9 semester-hour course for students of the social sciences. The illustrative materials and problems are taken chiefly from data of economic significance. The plan is "to interpret statistical science so far as this is possible under the assumption that the reader is equipped only with a good knowledge of college algebra."

The several chapters include preliminary analysis of statistical data, the graphical analysis of data—elementary curve fitting, methods of averaging, index numbers, the analysis of time series, analysis of artificial data—probability, binomial frequency distributions, the normal frequency curve—problems in sampling, curve fitting, elements of correlation, multiple and partial correlation, and types of statistical series. Appendixes include biographical notes on early mathematical economists, an explanation of logarithms, a brief exposition of the use of tables, and a number of mathematical and statistical tables.

FOODS—HUMAN NUTRITION

[Food and nutrition studies of the Massachusetts Station] (*Massachusetts Sta. Bul. 339 (1937), pp. 23, 24, 34, 35, 67-71, 72, 73*).—Included in this progress report are summaries of studies, several of which represent a continuation of earlier work (E. S. R., 75, p. 563), by W. B. Esselen, Jr., and J. E. Fuller on the effect of raw, pasteurized, and iodized milk on the fecal flora of white rats (pp. 23, 24); by W. S. Ritchie, G. C. Crooks, and C. R. Fellers on the chemical composition and nutritive value of haddock as affected by different freezing methods (pp. 34, 35); by H. S. Mitchell and G. M. Cook on the cause and control of nutritional cataract (p. 67); by Mitchell and M. Goldfaden on the source and amount of iodine effective in the prevention of the pathology produced in rabbits and guinea pigs by feeding cholesterol (p. 68); by Cook on the use of banana and milk in diets for weight control (p. 68); by Fellers, J. A. Clague, and A. S. Levine on apples and apple products (p. 69); by Fellers, C. F. Dunker, and D. DeFelice on the stability of vitamin C in sweet corn, lima beans, and spinach preserved by cooking, canning, and freezing (pp. 69, 70); by O. Merriam and Fellers on the vitamin content and other nutrition studies with blueberries (p. 70); by Fellers, W. A. MacLinn, and Levine on processing methods in home canning (p. 70); by MacLinn, Fellers, and R. C. Buck on tomatoes and tomato juice as antiscorbutics (p. 70); by Esselen and Fellers on the reliability of the dealers' guarantees of the vitamin D content of vitamin D milk in the State (p. 71); by Fellers, Clague, and D. A. Bean on the vitamin A and D content of whiting-liver oil (p. 71); by Fellers, V. Jancik, and Levine on the preservation of sweet peppers, melons, and cucumbers by salting and fermentation (p. 71); by K. Newman, Fellers, and M. J. Mack on the use of dextrose as a partial substitute for sucrose in the preparation of crushed fruits and sirups (p. 72); by Fellers, Clague, Esselen, and Levine on the preparation of cranberry juice and cordial (p. 72); by Esselen and Fellers on the influence of iodine and vitamin D on scurvy in guinea pigs (p. 72); and by Esselen, B. Isgur, and Fellers on the effect of variety and stage of growth on the vitamin A, C, and D content of corn (p. 73).

Recent developments in the chemistry of storage and preparation of foods, M. A. BARMORE (*Food Res., 1 (1936), No. 5, pp. 583-598*).—In this contribution from the Colorado Experiment Station, the author lists a few recent advances "from the 'art' to the 'science' stage" in food preparation and reviews recent advances in four fields of research in which there has recently been marked progress—storage of eggs, storage of potatoes, rancidity of fats and

oils, and pectin in its relation to jelly making. An extensive bibliography is appended.

Steam pressure method of canning necessary for high altitudes, W. V. HALVERSEN (*Idaho Sta. Bul. 221 (1937), pp. 26, 27*).—Data are presented on the time in minutes necessary to destroy spores of *Clostridium botulinum* in seven fruits and vegetables at pH varying from 3.60 to 6.95 and temperatures of from 90° to 115° C. It is recommended that at 90°, which corresponds to the boiling point of water at an altitude of 9,000 ft., the following processing times should be substituted for the exposures given in the commercial time tables: For hominy 10 hr., corn 9¼, spinach and beans 8½, pears 2¼, and prunes 1 hr.

The effect of temperature and time of cooking on the tenderness of roasts, S. COYER (*Texas Sta. Bul. 542 (1937), pp. 61, figs. 6*).—In this study the well-done roasts were cooked in a gas oven at constant temperatures of 125° and 225° C. to an internal temperature of 80°. Rib, round bone chuck, and rump roasts of beef, a half-ham roast of pork, and a leg of lamb roast were used. In a second series rib and round bone chuck roasts of beef were cooked to an internal temperature of 55° when the oven temperature was 125° and to 45° when the oven temperature was 225°, so that a maximum internal temperature close to that for medium rare (63°) was attained.

The results from the paired eating method (E. S. R., 76, p. 126), according to a panel of 12 judges, show that the well-done roasts may be grouped into three classes: The round bone chuck and rump roasts, which had the largest percentage of judgments in favor of the low oven temperature, the half-ham of pork and the rib roasts, which had a lower majority, and the leg of lamb, which had no significant majority in favor of the low oven temperature. Interpretations of the corresponding time-temperature curves for each of these cuts and of the difference in total cooking time between the high and low oven temperature methods give similar groupings. Contrary to the results with the other roasts, the time-temperature curves for the chuck and rump roasts cooked at the lower oven temperature flatten very abruptly at about 63°, and at least half of the total cooking time is required to raise the internal temperature from the medium to the well-done stage. The flattening affords evidence of either a chemical or physical change, accompanied by the absorption of heat in the internal temperature range between approximately 65° and 75°. A comparison of the roasts cooked to the medium rare stage showed no significant differences in tenderness either between the two cuts cooked at the same temperature or between the two methods of cooking. "The differences in tenderness, which in these tests have appeared to be related to oven temperature, seem to be explained in a more satisfactory manner on the basis of the length of time required for cooking." It would appear that the possibilities of obtaining a tender roast are greater when a low oven temperature is used.

Nutritive value of the blue crab (*Callinectes sapidus*) and sand crab (*Platyonichus ocellatus* Latreille), V. K. WATSON and C. R. FELLERS (*Amer. Fisheries Soc. Trans., 65 (1935), pp. 342-349, fig. 1; abs. in Massachusetts Sta. Bul. 339 (1937), p. 95*).—In this contribution from the Massachusetts Experiment Station, the literature on the composition and nutritive value of crab meat is reviewed and proximate and mineral analyses are reported on the edible meat of the blue crab and the sand crab. Data are also reported on the biological value of the proteins of the two species. With the exception of one lot of solidly frozen meat of the sand crab, the samples used for the analyses were of fresh unfrozen material. In the biological tests one sample of canned blue crab and three of frozen were used. All samples were dehydrated in a current

of air on large shallow glass pans in an oven at a temperature of from 95° to 104° F., ground to a fine powder, and stored in sealed glass bottles until used.

The meat from both species was very similar in composition, but differed from animal meat in having a high ash content and high alkalinity of the ash. The caloric values were moderate, 77.2 and 89.8 calories per 100 g, wet basis, for the blue crab and sand crab, respectively. The fat content was low, 0.39 and 0.24 percent, respectively. Values for the more important mineral elements were calcium 0.133 and 0.134, phosphorus 0.038 and 0.047, iron 0.002 and 0.0015, and copper 0.0013 and 0.0012 percent, respectively. Iodine values were 322 and 464 parts per billion.

In feeding experiments on young rats, crab meat fed at a 9 percent protein level in diets considered adequate in all other respects proved definitely superior in growth-promoting properties to either technical or vitamin-free casein. The sample of canned crab meat, while superior to casein, was definitely inferior to two samples of frozen blue crab and one of frozen sand crab meat.

Milk, N. N. GONBORE (*Benares, India: Author, 1936, pp. [2]+XVII+139, pls. 11*).—The purpose of the book is to disseminate a correct knowledge of milk as the most perfect food. The uses of milk and milk products are presented, with tables on the composition of different types of milk, butter, cheese, cereals, pulses, fruits and vegetables, and animal and vegetable foodstuffs. A foreword by M. M. Malaviya is included.

Nutritive value of chocolate flavored milk, W. S. MUELLER and W. S. RITCHIE (*Jour. Dairy Sci., 20 (1937), No. 6, pp. 359-369, figs. 3*).—In an experiment conducted by the Massachusetts Experiment Station, four groups of rats were fed ad libitum mineralized whole milk diets containing no cocoa and 4, 7, and 10 percent of cocoa, respectively. Under these conditions the rate of milk consumption and the average daily gain in weight decreased as the percentage of cocoa increased. In other experiments with rats on a whole milk powder-cane sugar basal diet to which cocoa was added at the rate of 0, 1, 2.5, and 4 percent, respectively, on a fluid milk basis and employing the principle of paired feeding, the 1-percent cocoa diet was equal to the whole milk diet; the 2.5-percent cocoa ration gave a questionable retardation of growth; and the 4-percent cocoa diet definitely retarded growth. The results obtained failed to determine the specific factors responsible for this retardation in growth. Feeding 7- or 10-percent cocoa resulted in the feces in the intestinal tract being very hard. There were no significant changes in the bacterial flora of the intestines for the whole milk and the 1- and 4-percent cocoa diets, and adding 1-percent cocoa had no significant effect on the fecal pH.

Composition and nutritive studies on blueberries, O. A. MERRIAM and C. R. FELLERS (*Food Res., 1 (1936), No. 6, pp. 501-512; abs. in Massachusetts Sta. Bul. 339 (1937), p. 98*).—In continuation of a previous study (*El. S. R., 70, p. 277*) at the Massachusetts Experiment Station, the authors report chemical analyses of fresh and moisture-free blueberries of wild highbush (*Vaccinium corymbosum*) and lowbush (*V. pennsylvanicum*) species native to Massachusetts and Maine, and four varieties of cultivated blueberries grown in Massachusetts and New Jersey. The vitamin A content was determined by the U. S. P. Revision (1934) technic, with the fresh blueberries fed at the 3- and 5-g levels and the dried blueberries at the 0.5-g level. The biological assay for vitamin C was again made by the Sherman-LaMer-Campbell method on fresh blueberries in season and on solidly frozen fruit, some samples of which had been defrosted and refrozen, during the remainder of the study,

and on kettle-cooked canned wild blueberries. The ascorbic acid content was determined by the Bessey and King titration technic (E. S. R., 71, p. 137).

The moisture content averaged 84 percent in wild highbush and from 76 to 85 percent in three varieties of cultivated highbush blueberries. The soluble solids (sugars) in the fresh fruit had a mean value of 11.6 percent, and the ash analysis showed the presence of from 1.25 to 1.58 percent of the usual minerals found in plant tissues, with a definite excess of alkaline elements. The protein content on the moisture-free basis varied from 3.14 to 4.69 percent, the fat content from 2.13 to 4.69, and the fiber content from 5.16 to 12.58 percent.

Limited data from the vitamin A determinations show a content of approximately 1 international unit per gram. Unless defrosted and refrozen, the frozen blueberries were found to be as good a source of vitamin C as the fresh fruit, with an estimated protective dose ranging between 7 and 10 g. From 10 to 20 g was the protective dose for the kettle-cooked canned blueberries. Very slight varietal differences were noted among the cultivated fruits, with the Rubel and Cabot varieties slightly higher in ascorbic acid content than the Harding and Pioneer. The four cultivated varieties ranged from 1 to more than 1.3 and the wild blueberries, when frozen or canned, from 0.5 to 1.6 international units of vitamin C per gram. It is concluded that blueberries are only a fair source of vitamins A and C.

Neither the blood alkaline reserve nor the urinary acidity was affected by the ingestion of 800 g of fresh blueberries daily by two adult males. The benzoic acid content of two lots of wild highbush blueberries was approximately 0.002 percent. See also previous comparable work with cranberries (E. S. R., 70, p. 866; 72, p. 191).

A system of judging flavour in bread, A. M. MAIDEN (*Jour. Soc. Chem. Indus., Chem. and Indus.*, 55 (1936), No. 8, pp. 143-145, fig. 1).—In the method described for investigating the effect of adding various substances to bread, the flavor was divided into (1) the strength of the smell, (2) the desirability of the smell, and (3) the desirability of the taste, with emphasis placed on the first two factors. The panel of judges was selected from the results of a test in which they placed loaves of bread containing varying amounts of ground-up crust to alter the strength of the flavor, in order of strength of smell. Two-lb. loaves baked in closed tins were found to be more uniform in flavor than those baked in open tins. The bread was judged when about 18 hr. old and not more than four persons judged one loaf.

The method was successfully applied to a study of the effect on bread flavor of acetylmethylcarbinol and diacetyl. No increase was found in the desirability of the flavor of the bread by the addition of either substance. It is concluded that neither of these substances is responsible for the normal flavor of English bread.

Homemade bread, cake, and pastry, F. B. KING and A. B. FREEMAN (*U. S. Dept. Agr., Farmers' Bul.* 1775 (1937), pp. 11-30).—In this bulletin, which is a revision of and supersedes Farmers' Bulletin 1450 (E. S. R., 54, p. 86), the materials used in bread, cake, and pastry making are discussed and 33 recipes are given, together with score cards for use in judging home baked products.

Growth and basal metabolism, V, VI, I. NAKAGAWA (*Amer. Jour. Diseases Children*, 53 (1937), No. 4, pp. 985-999).—In continuation of the series previously noted (E. S. R., 74, p. 129), two papers are presented.

V. Basal metabolism of high school children (pp. 985-990).—This report covers a study of the basal metabolism, as determined in the spring of the year by the technic previously described (E. S. R., 72, p. 721), of 23 healthy Japanese children between the ages of 12 yr. 1 mo. and 15 yr. 3 mo. Data on the physical

characteristics of the children are given. Coefficients of correlation between the total heat production and the physical factors weight, height, and surface area were determined from the data of various authors for children at puberty.

Comparing the average number of calories per square meter per hour as calculated by these authors will give a general view of the basal metabolism at puberty, but due largely to the small number of cases studied considerable discrepancy exists between their results. No conclusion is drawn as to which of the physical factors is the best for expressing the basal heat production of children at puberty.

The total heat production of Japanese high school children is low in comparison with the Talbot standards.

VI. *Changes in the basal metabolism of children during puberty* (pp. 991-999).—Following the method previously described, the basal metabolism, together with the body weight and height, of 24 Japanese children aged from 3 yr. 7 weeks to 13 yr. 4 mo. was studied every 6 mo. throughout the pubertal period. All tests were made in the spring and autumn seasons. The coefficients of correlation between the total heat production and the physical factors weight, height, and surface area were determined for the individual children.

An increase in total heat production was noted, beginning at the age of 11 or 12 yr. in the boys and 10 or 11 yr. in the girls and reaching the maximum at the age of 12 or 13 yr. in the boys and 11 or 12 yr. in the girls. The increase in weight and height continued until the age of 15 or 16 yr. in the boys and 14 or 15 yr. in the girls. In the individual children the physical factor weight was most closely correlated with the total heat production, but no conclusion was reached as to which factor is the best for expressing the amount of heat produced. The increase in the total heat production, which probably occurs in preparation for the physical changes which take place at puberty, reached the maximum at the average age of 14 yr. for the boys and 13 yr. for the girls, which is consistent with the earlier pubescence of girls.

The basal metabolism of normal boys and girls from two to twelve years old, inclusive, R. C. LEWIS, G. M. KINSMAN, and A. ILIFF (*Amer. Jour. Diseases Children*, 53 (1937), No. 1, II, pp. 348-423, figs. 30).—The results of 366 basal metabolism tests on 52 boys and 271 on 41 girls, aged from 2 to 12 yr., inclusive, are presented. The open circuit chamber method was followed, using the Carpenter-Haldane gas analysis apparatus. The amount of heat produced was expressed as calories per hour referred to age, weight, height, and surface area, respectively, and as calories per hour per square meter of surface area, per kilogram of body weight, and per centimeter of total height, respectively, referred to age. A detailed review of the literature covers basal metabolism studies on approximately 2,000 normal children within the age group of 2-12 yr., and the data reported by the various investigators were analyzed in relation to the central trend values obtained by the authors.

Statistical analyses showed that the mean coefficients of variation were lowest when the amount of heat produced was expressed as calories per hour referred to surface area for the boys, and calories per hour referred to weight for the girls, with the second lowest degrees of dispersion resulting in both groups when the heat production was expressed as calories per hour per square meter referred to age. These three sets of central trend line values are recommended as prediction standards and may be used equally satisfactorily for computing the basal metabolic rate of children aged from 2 to 12 yr., inclusive.

Basal metabolism of girls: Physiologic background and application of standards, F. B. TALBOT, E. B. WILSON, and J. WORCESTER (*Amer. Jour. Diseases Children*, 53 (1937), No. 1, II, pp. 273-347, figs. 10).—Statistical and clinical

analyses were made on groups of data, and basal metabolism standards were selected for girls from 12 to 20 yr. of age. The technics of various investigators and the effects of cretinism, hyperthyroidism, malnutrition, and obesity on basal metabolism are discussed. Comparisons were made with predictions obtained from the average weight standard proposed by the authors and the Aub-Du Bois and Harris-Benedict standards for older children and the Kestner-Knippling standard for younger children.

A definite relationship between body weight and heat production was demonstrated, and it was found mathematically that "total calories for the weight" gave the closest fit of any method used for predicting calories for the group of girls studied. The application of a correction for age improved the correlation. The standards should also be corrected for different localities but not for racial differences. Considerable evidence is presented to show that there is a relationship between the speed of growth and surplus metabolism, and that the elevation in metabolism seen just before puberty is not due to puberty of itself but to the speed of growth.

A comparison of four current methods of estimating physical status, E. L. MARSHALL (*Child Develpmt.*, 8 (1937), No. 1, pp. 89-92).—When four methods of estimating physical status were applied to a group of 77 boys between 7 and 12 yr. of age, the results obtained by the application of the Baldwin-Wood age-height-weight tables and the McCloy age-height-hip-chest-knee-weight standards were similar, while those secured by the Franzen and Palmer ACH Index and the Pryor and Stolz age-hip-height-weight standards were dissimilar. Subjects with a low percentage according to one method were frequently in the normal zone according to another.

A stack of constant volume for respiration experiments with humans, F. G. BENEDICT (*Jour. Biol. Chem.*, 116 (1936), No. 1, pp. 307-320, fig. 1).—An open circuit respiration apparatus is described in which the expired air is collected in an elongated pipe or stack of known and constant value. The basic principle rests upon the stratification of the expired air by controlling the temperature and humidity conditions at the bottom of the stack and its slow rate of diffusion with the outdoor or room air already in the stack due to the difference in densities. The subject breathes through a mouthpiece connected with inspiratory and expiratory valves and as the expired air accumulates in the bottom of the stack it gradually expels the outdoor air from the top. After 10 min. the stack is made into a closed circuit system and the air inside is thoroughly mixed before a sample is withdrawn for gas analysis. The carbon dioxide production and the oxygen consumption of the subject are calculated. The apparatus functions accurately to within the slight error inherent in gas analysis by the Haldane method.

Protein, salt, and fluid consumption of 1,000 residents of New York, B. I. ASHE and H. O. MOSENTHAL (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 14, pp. 1160-1163).—The determination of the amount of protein, salt, and fluid intake was based on the nitrogen, sodium chloride, and total fluid output in the 24-hr. urine. An allowance of 10 percent was made for nitrogen loss in the feces. The majority of the 1,000 individuals studied took a low protein, moderately high salt, and moderate fluid ration. Only 7 percent of the group ate 75 g or more of protein, while 61 percent ate 42 g or less, 53 percent took over 8 g of salt and 5 percent took 4 g or less, and 39 percent had a fluid intake of 1,500 cc, while 25 percent took 1,000 cc or less daily. "While the normal individual eating a low protein diet tends to have a low blood pressure and a low hemoglobin percentage, the normal person eating a high protein diet has no increased blood pressure and his hemoglobin is normal. The

high protein diet has less effect in raising the blood urea nitrogen than has a low fluid intake."

Observations on human subject subsisting six months on a diet extremely low in fat, W. R. BROWN, A. E. HANSEN, I. MCQUARRIE, and G. O. BURR (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 3, pp. 281-283).—Observations were made on a normal adult maintained for 6 mo. on a diet consisting of skim milk, sucrose, potato starch, baking powder, sodium chloride, and orange juice, with vitamin and mineral supplements and containing about 2 g of fat. The level of cholesterol or total fatty acids was unchanged, but the iodine number of the serum fatty acids fell approximately one-third and the arachidonic and linoleic acids of the serum decreased, the hemoglobin and red blood cells remained essentially the same, a definite tendency to leucopenia was noted, and the fasting blood sugar level, the glucose tolerance curve, and the urine remained normal. After about 4 mo. the average blood pressure reading was approximately 10 mm of mercury lower. The weight gradually decreased during the first 3 mo. on the low fat diet. No definite trend in metabolic rates was noted, but higher respiratory quotients were found at the end of the 6-mo. period. The physical condition remained unchanged, the amount of fatigue decreased, and migraine attacks previously occurring ceased after 6 weeks.

Water intake and the blood sugar level, M. C. HEUBETZ (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 3, pp. 420-422, fig. 1).—Observations were made to determine the influence, if any, of the water consumption by the open jar and the tubulated bottle upon the blood sugar level of 30 rats representing the fourth, fifth, and sixth generations, which had been kept continuously on a high carbohydrate diet, and on normal control animals.

Blood sugar levels, which were high during the period when the water was supplied in tubulated bottles, promptly dropped to a lower level in the control animals when the bottles were replaced by open water jars. The high carbohydrate rats maintained the high blood sugar for 3 weeks and returned to normal during the fourth week. Although no explanation of the mechanism involved is advanced, the findings are deemed of importance in the standardization of experimental equipment.

Symptomatology and pathology of potassium and magnesium deficiencies in the rat, G. A. SCHRADER, C. O. PRICKETT, and W. D. SALMON (*Jour. Nutr.*, 14 (1937), No. 1, pp. 85-109, figs. 8).—In this study at the Alabama Experiment Station a basal ration of ground yellow corn, wheat middlings, and casein, each extracted as described, and cod-liver oil (59 : 25 : 12 : 1) was employed. One experimental group of rats received a salt supplement of sodium chloride, calcium carbonate, tricalcium phosphate, and trihydrated magnesium sulfate (1 : 1 : 1 : 0.5) and the other a supplement of calcium carbonate, tricalcium phosphate, potassium chloride, and sodium bicarbonate (1 : 1 : 1 : 1.4). A negative control lot received neither potassium nor magnesium supplement, and positive control lots received both potassium and magnesium either as simple salts or as parts of a complex salt mixture.

The rats on the potassium-deficient magnesium-sufficient diet showed slow loss in weight, this loss being of about the same order as in that of the negative controls. These animals were characterized by short furlike hair, cyanosis, abdominal distention, and lethargy resulting in coma, with death occurring on the average at 23 days. Pathological changes were noted in the intestines, pancreas, kidneys, and heart, and a marked accumulation of serous fluid occurred usually in the abdominal cavity, and occasionally in the hydrothorax and hypopericardium. The rats on the magnesium-deficient potassium-suf-

ficient diet made very subnormal growth during the early stages and later lost weight before death occurred. Skin disorders characterized by general hyperemia followed by circumscribed areas of erythema, hemorrhages, eschar formation, and exfoliation consistently developed. Edema of the extremities and nasal region occasionally occurred. A hyperirritability of progressive intensity developed, leading to convulsions (average 30 days) and death (average 35 days). Little histopathology was encountered, although about one-third of the cases showed degenerative changes in the liver. The negative control rats showed symptoms similar to those on the potassium-deficient diet and in addition developed the hyperirritability of magnesium deficiency. Positive controls appeared normal except that growth was somewhat subnormal.

Dark adaptation and vitamin A.—A new photometric technic, P. C. JEANS, E. BLANCHARD, and Z. ZENTMIRE (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 6, pp. 451-458, figs. 10).—A biophotometer devised from the Birch-Hirschfeld instrument previously described (*El. S. R.*, 71, p. 566) and a technic for its use in the determination of the ability of the human eye to adapt to darkness are presented. Experimental observations made with the new instrument demonstrated that vitamin A deficiency is more frequent than has been generally assumed, and that the biophotometer reveals a higher proportion of moderately subnormal subjects than did the previous instrument.

In a group of 37 school children, 19 percent were subnormal and 5 percent borderline cases of vitamin A deficiency, while of 23 orphanage children 8 showed abnormal test results by the new technic. Observations made on two 11-year-old boys indicate that 3,000 units of vitamin A a day is adequate when the biophotometer test is used as the criterion.

Night blindness due to vitamin A deficiency: A consideration of its importance in traffic problems, H. JESHERS (*New England Jour. Med.*, 216 (1937), No. 2, pp. 51-56).—Personal observations on subjects tested for avitaminosis A by a Birch-Hirschfeld photometer and data obtained from the literature are presented to show that night blindness (hemeralopia) due to vitamin A deficiency decreases the efficiency of automobile driving at night and increases the probability of accidents. At present no test for the presence of essential hemeralopia is required for either automobile drivers or aviators.

The use of various rat assay methods in comparing crystalline vitamin B₁ preparations, F. F. HEYBOTH (*Biochem. Jour.*, 30 (1936), No. 4, pp. 645-650).—In continuation of the study of the parallelism between the ultraviolet absorption spectra of vitamin B₁ preparations and their potencies (*El. S. R.*, 69, p. 325), three samples of crystalline vitamin B₁ (Peters' preparation 64:19, oryzanin from yeast, and oryzanin from rice polishings prepared by Ohdake) were tested on rats with nervous symptoms induced by a deficiency of this vitamin. The criteria of potency used were the minimal dose needed to cure, the number of days after a single dose the animals remained free of symptoms, and the number of days after a single dose before the weight increase was lost again.

The three preparations consisted essentially of the same physiologically active material, since practically identical results were obtained as judged by all three criteria. The minimum dose for each preparation was approximately 3 γ . The rat day dose was found to be 0.41 γ for the Peters preparation, 0.509 γ (yeast) and 0.45 γ (rice) for the oryzanin preparation of Ohdake. Statistical analysis of the results showed that the standard mean variation, when expressed as a percentage of the mean value and with the abnormal cases omitted, was from 35 to 44 for the day dose method and from 37 to 63 for the weight maintenance method. Therefore, the day dose method gave the more accurate

results. The values found for the day doses were influenced by the length of the curative period. The day doses required to prevent the recurrence of severe symptoms in rats and pigeons were proportional to the mean weights of the animals at the times of injection. The minimum curative dose for the rat was found to be 1.2 times the pigeon day dose and 6.6 times the day dose required for preventing the recurrence of severe symptoms.

The vitamin B₁ content of grain studied in comparison with the international standard for vitamin B₁ [trans. title], V. FAMIANI (*Atti. R. Accad. Naz. Lincei*, 6. ser., *Rend. Cl. Sci. Fis., Mat., e Nat.*, 24 (1936), No. 3-4, pp. 88-93).—Four normal adult pigeons receiving 30 g daily of polished and washed rice were used in the investigation. The effects of adding, in equal doses over a 10-day period, 50, 100, 150, and 200 units, respectively, of the international standard vitamin B₁ were compared with the effects of adding 20, 30, 40, and 50 g, respectively, of Villa Giori grain. The beriberi quotient "Q_b" values were determined.

The addition to the basal diet of 50-100 units of the international standard vitamin B₁ gave Q_b residue values of 0.13-0.22, which were approximately equal to the values of 0.13-0.21 given by the addition of 20-30 g of the grain. It was concluded that 1 g of the grain contained approximately 2.5-3 international units of vitamin B₁. When the supplements were increased the relationship was not as close. The 40-g supplement of grain gave a value of 0.23 as compared with 0.43 when 150 international standard units were administered. When the pigeon received a 50-g supplement of grain, the value was 0.28 as compared with 0.38 for the 200-unit dose of the standard. The amount of vitamin B₁ contained in 5 g of the grain was shown to be the approximate daily dose necessary to keep the pigeon in equilibrium with no loss of vitamin B₁.

Lesions of the nervous system of the rat in vitamin B deficiency, C. DAVISON and L. STONE (*Arch. Path.*, 23 (1937), No. 2, pp. 207-223, figs. 5).—Groups of experimental rats were placed on diets totally and subtotally deficient in vitamin B₁ or in vitamins B₁ and B₂, and groups of control rats were fed stock diets or artificial diets containing adequate vitamin rations, or were subjected to total starvation and starvation despite adequate vitamin rations. Clinical and microscopical observations were made on the nervous system.

The rats maintained on the experimental diets partially or wholly deficient in vitamin B₁ or vitamins B₁ and B₂ showed neurological signs such as dragging and paralysis of the extremities, equilibrium disturbances, priapism, convulsions, and tonic retractions of the head. The pathological changes found were disintegration of the myelin sheaths of the peripheral nerves and vacuolation and liquefaction necrosis of the ganglion cells of the mesencephalon, metencephalon, and anterior horns of the spinal cord, with hemorrhages accompanying changes in the ganglion and glia cells of the mesencephalon noted in animals with convulsions. Essentially the same pathological changes, but not as marked, were found in the animals partially or wholly starved, with and without adequate vitamin rations. Because of the rapid death of the starved animals, the clinical manifestations were not identical with those observed in animals suffering from vitamin B deficiency.

Biosynthesis of ascorbic acid. B. C. GUHA and B. GHOSH (*Nature [London]*, 158 (1936), No. 3498, pp. 844, 845).—It is noted briefly, with confirmatory data, that molecular oxygen is necessary for the in vitro synthesis of ascorbic acid in the liver tissue of the rat on incubation with mannose.

Ascorbic acid in gastric juice, G. A. PETERS and H. E. MARTIN (*Soc. Exptl. Biol. and Med. Proc.*, 36 (1937), No. 1, pp. 76-78).—Samples of gastric juice from nine dogs showed a range in vitamin C content from 0.33 to 1.51 mg and an

average value of 0.692 mg per 100 cc. Corresponding values for human gastric juice from 12 hospitalized patients were 0.046-1.04, and 0.397 mg per 100 cc. Analyses of the mucous membranes of different parts of the gastrointestinal tract of two dogs showed the highest concentration of vitamin C to be in the duodenal mucosa, followed by the iliac and colic mucosa and the fundic and pyloric portions of the stomach.

Cataract and ascorbic acid in the guinea-pig eye, S. W. JOHNSON (*Biochem. Jour.*, 30 (1936), No. 8, pp. 1480-1487, figs. 4).—The spectrophotometric method in conjunction with the indophenol titrimetric method was employed in determining the ascorbic acid content of the humors and lenses of the guinea pig, horse, ox, sheep, and pig. Determinations were also made on guinea pigs maintained on a scorbutic diet during the depletion of vitamin C and following the administration of prophylactic doses of ascorbic acid.

The titration method gave values in close agreement with those of the spectrophotometric method for the humors of normal animals and slightly higher values for the lenses. The ascorbic acid content of the humors and lenses became almost equal to zero after the guinea pigs had been on the scorbutic diet for 9 days. The rates of disappearance from the humors and lenses during depletion and reappearance of vitamin C after administration ran parallel with those of the other tissues. No cataract appeared in animals deprived of vitamin C.

An excretory test for vitamin C deficiency and subnutrition, E. P. RALLI, G. J. FRIEDMAN, and M. KASLOW (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 1, pp. 52-54).—To determine the feasibility of using less than 24-hr. urines in tests for vitamin C saturation, 12 normal adults on diets adequate in vitamin C, 3 normal adults on diets low in vitamin C, and 13 patients with scurvy were subjected to the following tests:

The vitamin C excretion was determined by the customary titration for a 3-hr. period and the following 21-hr. period before the administration of vitamin C. The next day after the bladder had been emptied an intravenous injection of 100 mg of ascorbic acid was given and the urine again tested during the 3-hr. and 21-hr. periods. The subjects in the first two groups were from 20 to 25 yr. of age, while in the third group 5 of the subjects were under 40 yr., 3 between 40 and 60, and 5 over 60 yr. of age.

In the subjects of the first group the urinary excretion of vitamin C before administration of the test dose ranged from 4.5 to 25 mg in the 3-hr. period and from 31 to 180 mg in the following 21 hr., with averages for the two periods of 12 and 67 mg. In the second group the 3-hr. excretion averaged 2 mg and the 21-hr. excretion 10 mg. In the third group the highest value for the 3-hr. sample was 3.3 mg, and in some cases no vitamin C could be detected either in the 3-hr. or in the 21-hr. sample. Following the test dose, the subjects in the first group excreted an average of more than 40 percent of the injected vitamin within 3 hr., in the second group an average of 11 percent, and in the third group an average of 2.6 percent.

"These observations support the fact that the 3-hr. urinary excretion of vitamin C following an intravenous dose of 100 mg of ascorbic acid will serve as an index of vitamin C deficiency or subnutrition."

The multiple nature of vitamin D, C. E. BILLS (In *Cold Spring Harbor Symposia on Quantitative Biology*, III. Cold Spring Harbor, N. Y.: Biol. Lab., 1935, vol. 3, pp. 323-340).—This is a concise chronological review of the development of knowledge of the D vitamins from their first differentiation from vitamin A by McCollum et al. in 1922 to the middle of 1935. A list of literature references and an abstract of a discussion of the paper are included.

Technique of the line test assay for vitamin D, A. L. BACHARACH, E. ALLCHORNE, and H. E. GLYNN (*Biochem. Jour.*, 30 (1936), No. 11, pp. 2004-2006).—The Coward single dose method (*E. S. R.*, 73, p. 720) of feeding vitamin D supplements in the line test was compared with the divided dose method on 12 litters of rats receiving a diet more severely rachitogenic than the Steenbock ration 2965. The divided dose method gave significantly better healing as judged from examination of the femurs instead of the ulnae and radii. There were indications that the male rats under the conditions of the experiment responded slightly better to cure by a given dose than did the females.

Estimation of vitamin D in blood serum, J. WARKANY (*Amer. Jour. Diseases Children*, 52 (1936), No. 4, pp. 831-847, figs. 2).—The author describes a series of preliminary studies on rabbits to estimate the vitamin D content of normal and pathological blood serums, together with a number of estimations on normal human serums. The vitamin D content of the serum samples was estimated by determining the amount of serum required to cure rachitic rats.

A change of the vitamin D level of the blood serum following the oral administration of 0.1 cc of viosterol (100,000 U. S. P. units) was demonstrated, the peak of the curve which was reached in 24 hr. being maintained until about the fourth day and then slowly decreased, until after from 4 to 6 weeks the elevation was no longer manifest. "The period between the first and the fourth day, the time of a constant high level, is recommended for the examination of factors that might influence the vitamin D level." Ether anesthesia, starvation, or fever did not influence the vitamin D level, nor were the blood phosphorus, calcium, or phosphatase contents changed when viosterol was administered. Following the administration of 1 cc of viosterol (1,000,000 U. S. P. units), values as high as 54,000 U. S. P. units per 100 cc of blood serum were obtained.

In 48 estimations on human blood serums, values of from 45.9 to 135 U. S. P. units of vitamin D per 100 cc were obtained, with an average value of 99.09.

Comparative investigation on rats and chickens dealing with the identity of the artificial antirachitic vitamin (irradiated ergosterol) and the natural vitamin D of cod liver oil, M. J. L. DOLS (*Vergelijkend onderzoek op ratten en kuikens over de identiteit van het kunstmatige antirachitische vitamine (bestraald ergosterol) en het natuurlijke vitamine D uit kabeljauw-levertraan. Proefschr., Landb. Hooges., Wageningen, 1935, pp. [9]+139, pls. 2; Eng. abs., pp. 118-125*).—The basal ration of both rats and chickens contained yellow corn 144 parts, wheat middlings, 60, crude casein 30, dried brewers' yeast 3½, calcium carbonate 10, and common salt 2½ parts. The calcium:phosphorus ratio was approximately 4.2 and the phosphorus content 0.45 percent. Varying amounts of the test oils and concentrates were mixed with the basal ration. The standard tests on albino rats were followed by the main tests with White Leghorn chickens. By means of radiographs and observations on bone deformities of the skeleton, the presence of rickets was determined.

Two percent of cod-liver oil protected the chickens against rickets, while irradiated ergosterol in an amount equivalent to the rat units of vitamin D in 20 percent of cod-liver oil failed to protect. The chickens were protected from rickets during the period of 1-57 days by the administration of 250 international units of vitamin D per 100 g of ration, or approximately 80 units per day per chicken, in the form of cod-liver oil, tunny-liver oil concentrate, or irradiated cholesterol. It is concluded that crystalline irradiated ergosterol differs from the vitamin D present in cod-liver oil, and that the provitamin D in cholesterol, activated antirachitically by ultraviolet irradiation, is not ergosterol. It is

considered that the radiograph is sometimes a more minute criterion than post-mortem examination of the skeleton when determining rickets in chickens.

The present status of vitamin D milk, F. C. BING ET AL. (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 3, pp. 206, 207).—A summary is presented by the Council on Foods of the American Medical Association of the requirements and allowable claims for vitamin D milks, considered from the nutritive point of view.

No claim or intimation may be allowed that an adequate amount of the vitamin is being supplied to infants for milks containing less than 185 units, but above this figure an enhanced nutritive value may be claimed and it may be stated that the milks usually will prevent clinical rickets when fed to normal infants in the amount of $1\frac{1}{2}$ oz. for each pound of body weight in early infancy and $1\frac{1}{2}$ pt. or more daily in later infancy. With 400 units per quart it may be claimed that the amount of vitamin D is greater than that usually required for the prevention of rickets in normal infants. The bottle caps and labels must declare the unitage of vitamin D in terms of U. S. P. units and the source of the vitamin D unless local governmental regulations prohibit such declaration. The foregoing statements also apply to evaporated milk diluted with an equal volume of water. "In the advertising of vitamin D milk the implication should not be made that the Council favors the use of any vitamin D fortified milk over the prescribing of other forms of vitamin D for infants or recommends the use of vitamin D milk to the exclusion of an additional supply of the vitamin in some other form."

The ultraviolet component of the sunlight of Portland, Ore., measured by the acetone-methylene blue method, II, I. A. MANVILLE (*Amer. Jour. Diseases Children*, 53 (1937), No. 1, I, pp. 39-55, figs. 6).—In continuation of the previous study (E. S. R., 62, p. 592) further observations were made to obtain data for the 2-yr. period ended February 6, 1930. The portion of the daily total of ultraviolet radiation between 10 a. m. and 1 p. m. was also determined.

The daily average of ultraviolet radiation for 1928-29 was 3.36 units and for 1929-30 it increased to 6.2 units, due largely to a 26 percent increase in the amount of sunshine and a 20 percent decrease in the amount of rainfall, while the average daily temperature at noon (54.3° F.) remained the same and the amount of smoke from forest fires was very much less. An average amount of 2.76 units or 44.5 percent of the daily total of ultraviolet radiation was received between 10 a. m. and 1 p. m. With the exception of 2 weeks when the radiation was less than 0.5 unit, the taking of a sun bath of from $1\frac{1}{2}$ to 3 h. during the middle of the day would provide protection against rickets. It is pointed out that, because of the mild noon temperature and the richness in ultraviolet rays of the sunshine at this time of day and because of the necessity of irradiating only a small part of the body at a time and at intervals which may be from 7 to 10 days, it is possible to treat rickets effectively the year around in Portland, Oreg.

The effect of nutrition on the primary teeth, F. F. TISDALE (*Child Developmt.*, 8 (1937), No. 1, pp. 102-104).—To determine whether lack of vitamin D has any effect on the development of tooth decay, 162 children living in an institution were divided into two groups, and in one group the diet, otherwise adequate, was supplemented by vitamin D. Dental examinations were made at the beginning and end of the 1-yr. experimental period. The group given the diet deficient in vitamin D showed an incidence of dental caries in the deciduous teeth more than double that found in the group receiving the vitamin D supplement. The author recommends the administration of a diet built around milk, meat, eggs, vegetables, and fruit, with added vitamin D and a com-

paratively low sugar content to decrease tooth decay and develop normal healthy teeth.

The avitaminoses, W. H. EDDY and G. DALLDORF (*Baltimore: Williams & Wilkins Co., 1937, pp. IX-338, pls. 29, figs. 3*).—This book is derived from The Vitamine Manual written by the senior author in 1921 (E. S. R., 46, p. 256). It has been enlarged to include pathological and clinical discussions of the vitamin deficiency diseases, descriptions of clinical methods for studying human cases, standard methods for bio-assays, and tables of vitamin values expressed in units per ounce. The vitamins A, B (B_1), C, D, E, and the antipellagic, antidermatitic factors of G (B_2) are listed as established vitamins, while the postulated vitamins are G (B_3)—flavine fraction of the B complex, B_4 —heat-labile bird factor, B_5 —heat-labile rat factor, B_6 —heat-stable bird factor, B_7 —curative and preventive of rat pellagra, P P body—human pellagra-preventive factor, vitamin D₂—the second calcifying factor in cod-liver oil, and F—designating a group of fatty acids containing two double bonds believed to be preventive of certain skin lesions.

A new group of alimentary constituents (alitoxins) and their corresponding pathologic effect [trans. title], L. A. TSCHERKES (*Jour. Physiol. et Path. Gén., 34 (1936), No. 3, pp. 808-814, figs. 3*).—Symptoms similar to those shown by vitamin B₂ deficiency and pellagra in man were noted in white mice receiving a diet consisting largely of cereal (corn, millet, wheat, rice, and buckwheat) or bran, and milk, yeast, and cod-liver oil. The administration of vitamin B₂ did not cure the disease. Under similar experimental conditions rabbits displayed symptoms of paralysis and convulsions. Autopsies revealed some histological changes, particularly in the liver. The disease was prevented when small amounts of cabbage or sugar beet leaves were added to the diet of the rabbits.

The name "alitoxicosis" was given to the disease, with the presence in the diet of specific constituents, alitoxins, believed to be the cause. One alitoxin has been shown to be the glucoside phaseolunatin contained in a type of bean grown in Asia. The alitoxins are destroyed by hydrochloric acid and some by heat. It is suggested that the normal gastric secretion may inactivate certain alitoxins. There is some evidence that the alitoxic agent is closely linked to the protein albumin and that it is toxic to both vegetable and animal organisms.

TEXTILES AND CLOTHING

Fleece density of sheep: The Wyedesa fleece caliper, R. H. BURNS (*Jour. Textile Inst., 28 (1937), No. 4, pp. T113-T128, figs. 3*).—The accuracy of the Wyedesa fleece caliper, as indicated by the variation between quadruplicate samples and by a comparison with contiguous quadruplicate samples, and the accuracy of engineer's calipers and the Wyedesa fleece caliper, as shown by the variation of replicate samples, are reported. Certain phases of the work were done at the Wyoming Experiment Station. The literature on fleece density determination is summarized.

A serviceability test on blankets made from four blends of wool, M. B. HAYS, R. E. ELMQUIST, and J. I. HARDY (*U. S. Dept. Agr., Tech. Bul. 572 (1937), pp. 24, figs. 12*).—In this study, conducted jointly by the Bureaus of Animal Industry and Home Economics, blankets were manufactured from four blends of wool selected from individuals of purebred flocks of Corriedale and Rambouillet sheep as follows: Rambouillet equal parts of fine and one-half blood, Corriedale 2 parts of three-eighths and 1 part of one-fourth blood, Corriedale

1 part three-eighths blood and 2 parts reworked wool, and a fourth lot from 100 percent reworked wool. Extensive records were available on the breeding and production of the sheep, including feeding and climatic conditions under which they were maintained. Service tests were made on 63 of the blankets, and their progressive deterioration was studied by measurements at intervals of the physical and chemical properties.

The four fabrics deteriorated progressively during finishing and with service, and in general the rate was greater for those containing reworked wool. The manufacturing process caused some fiber deterioration, as shown by scale breakage, methylene blue absorption, and by microscopical observations. The fabrics composed of equal parts of fine and one-half blood and of 2 parts three-eighths blood and 1 part one-fourth blood gave approximately the same service, and all the blankets were still serviceable after from 23 to 52 and 19 to 37 launderings, respectively. The rate of deterioration was slightly less for the former fabrics, as determined by air permeability, resistance to abrasion, sulfur, nitrogen, moisture content, and methylene blue absorption. However, judged by breaking and bursting strength, scale breakage, and resistance to bacterial infection, the latter fabrics showed a slightly lower rate of deterioration. The fabrics containing 1 part three-eighths blood and 2 parts reworked wool wore out after 36 launderings and showed less shrinkage and lower warmth protection than did the two previous groups of fabrics. The fabric made of all reworked wool afforded little warmth protection and was worn out after 12 launderings.

Classification of sheets as an aid to consumer buying, M. B. HAYES (*Rayon Textile Mo.*, 18 (1937), No. 3, pp. 71, 72, fig. 1).—An analysis of 39 brands of bleached cotton sheets is reported by the U. S. D. A. Bureau of Home Economics. On the basis of fillingwise thread counts, the sheets are divided into five classes: Percale, fine counts or utility percale, heavy weight, medium weight, and light weight muslins. The same groupings resulted when the values for breaking strength, weight, and percentage of sizing were compared. The maximum amount of sizing for each of the five classes was determined to be 1 percent for percales, 2 for fine counts and heavy weight muslins, 6 for medium weight, and 10 for light weight muslins. To enable the consumer to know how sheets on the market compare with the standards for the proposed classification, minimum specifications were set up for the thread count, breaking strength, and weight per square yard.

HOME MANAGEMENT AND EQUIPMENT

[Home management studies of the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1936], pp. 32-34).—Progress reports are given on studies of the kinds and maintenance of floor finishes best suited for household use, of methods by which the housekeeping activities are carried on in the home of the married woman who works full time outside the home, and of homemaking on part-time farms in the State. Data are included on the time spent on different home activities by women carrying on full-time jobs outside the home as compared with data reported in Bulletin 221 (E. S. R., 62, p. 598) and on the adequacy of the diet and extent of home improvements on part-time farms.

A study of quality demands in household buying of food, M. I. LISTON (*Vermont Sta. Bul.* 415 (1937), pp. 39).—The study was made of 120 household buyers living in Burlington, Vt., and representing homes of liberal, moderate, and limited income levels. To supplement the information gained by guided and unguided statements of the housewives concerning the characteristics of the products habitually purchased and the methods used to identify foods pos-

sessing the desired qualities, further information was obtained from the owners and managers of the food stores patronized and through actual observations made during the sale of seven commodities. The buyers were questioned concerning their knowledge of official grading and the use of grade labels. Only 17 percent had had any training in food buying. The following are the essential findings:

Butter was purchased by brand name by two-thirds of the housewives, the quality factors usually sought being mild flavor and a medium salt content. Eggs were purchased direct from the producers by two-thirds of the buyers, and only one-sixth bought better eggs for the table than for cooking. Medium colored, well-rounded yolks and thick whites were demanded for table use but not for cooking. Uniformity of size, color and shape, freedom from defects, firmness of texture, and a definite variety were the characteristics noted by examination in the purchase of eating apples, which were commonly bought from producers. Potatoes were generally bought from producers without examination or specification as to desirable characteristics. About three-fourths of the housewives requested their storekeepers to select for them young, broad, and full-breasted turkeys bearing the State green tag of quality. Beef roasts were often ordered by cut, with no specifications other than good fat mottling. Small Valencia oranges were preferred for juice and large navels for serving whole. Most of the housewives examined oranges at the time of purchase to get smooth-skinned fruit, heavy in comparison to size, and free of defects.

Little interest was expressed in the establishment of grades and standards for Vermont-grown food products other than turkeys and maple sirup. However, the general consensus of opinion was that canned goods should be officially graded and labeled accordingly.

A study of efficient kitchen arrangements, G. M. REDFIELD (*Indiana Sta. Bul. 418 (1937), pp. 29, figs. 14*).—The results of a survey made of 774 rural Indiana kitchens showed that many are inadequately equipped, inefficiently arranged, and vary in size from 6 by 7 ft. to 24 by 24 ft. A kitchen 12 ft. wide by 15 ft. long was selected as a standard and was set up in the laboratory and equipped with a range, refrigerator, sink, kitchen cabinet, serving table, chair, and storage cabinet, and space was allowed for 3 doors and 2 windows. The equipment was rearranged in 28 different ways, and the relative efficiencies of the different arrangements were determined by four tasks—the making of a plain cake and an apple pie and the preparation of a single meal and of a day's meals. A process chart was worked out for each task and varied to fit each arrangement.

In a well-equipped and well-arranged kitchen the housewife should be able to start at the storage center and carry through the meal preparations to the dining table with little retracing of steps or crossing from one work space to another. In a long narrow kitchen the equipment should be arranged around the end of the room, while in a square kitchen an L-shaped arrangement is more efficient. Work surface heights between 32 and 34 in. are satisfactory for the woman of average height. Sufficient light should be available at all work centers. The survey of kitchen storage needs disclosed the fact that storage space must be provided in or near the kitchen for about 450 items of canned goods, 30 kitchen utensils, 100 dishes, 72 pieces of silver, 66 pieces of linen, 15 to 20 bulk items such as cereals, 36 cakes of soap, and 7 brushes and handled cleaning tools. "Since farm homemakers spend an average of 54 hr. a week in homemaking activities, the kitchen should receive more thought and attention when planning the house than any other room."

MISCELLANEOUS

A history of agricultural experimentation and research in the United States, 1607-1925, including a history of the United States Department of Agriculture, A. C. TRUE (*U. S. Dept. Agr., Misc. Pub. 251 (1937)*), pp. VI+321, pl. 1, figs. 11).—This monograph has been discussed editorially (*E. S. R.*, 75, p. 737).

Report on the agricultural experiment stations, 1936, J. T. JARDINE, W. H. BEAL, ET AL. (*U. S. Dept. Agr., Off. Expt. Stas., Rpt. Agr. Expt. Stas. 1936*, pp. 208).—This report has been noted editorially (*E. S. R.*, 77, p. 433).

University of Alaska Agricultural Experiment Station, College, Alaska, [1935 and 1936: Progress reports], January-December, G. W. GASSER ET AL. (*Alaska Sta. Buls.* 5 [1936], pp. 28, figs. 12; 6 [1937], pp. 39, figs. 13).—The experimental work reported is for the most part noted elsewhere in this issue.

Science serves Idaho agriculture: The Annual Report of the [Idaho] Agricultural Experiment Station for the year ending December 31, 1936, C. W. HUNGERFORD ET AL. (*Idaho Sta. Bul. 221 (1937)*, pp. 53, figs. 13).—The experimental work not previously reported is for the most part noted elsewhere in this issue. Vitamin studies by E. Woods (pp. 33, 34) are included.

Forty-ninth Annual Report of [Kentucky Station], 1936, I, II, T. P. COOPER ET AL. (*Kentucky Sta. Rpt. 1936*, pts. 1, pp. 63; 2, pp. [3]+196, figs. 63).—Part 1 includes the report of the director, the experimental work referred to and not previously noted being for the most part abstracted elsewhere in this issue. Part 2 contains reprints of Bulletins 362-367 and Circulars 44 and 45, previously noted.

Annual report of the Massachusetts Agricultural Experiment Station, 1936, F. J. SIEVERS ET AL. (*Massachusetts Sta. Bul. 339 (1937)*, pp. 100).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-ninth Annual Report of the [Michigan Station], 1936, V. R. GARDNER (*Michigan Sta. Rpt. 1936*, pp. 81-99, 182-201).—The experimental work reported is reprinted from the biennial report previously noted (*E. S. R.*, 76, p. 733).

Annual Report of [Puerto Rico College Station, 1935], F. A. LÓPEZ DOMÍNGUEZ ET AL. (*Puerto Rico Col. Sta. Rpt. 1935*, pp. 166).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-ninth Annual Report [of Rhode Island Station, 1936], B. E. GILBERT (*Rhode Island Sta. Rpt. [1936]*, pp. 44).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data (pp. 42, 43) are also included.

Abstracts of Bulletins 523-538, Circulars 77-78, and other publications during 1936, A. D. JACKSON (*Texas Sta. Circ. 79 (1937)*, pp. 34).—IN addition to abstracts of the station's own publications as indicated, this circular contains abstracts of articles contributed by members of the staff for publication elsewhere. For the most part these have been either previously noted or abstracted elsewhere in this issue.

NOTES

California University and Station.—Samuel H. Beckett, associated with the irrigation work of the institution beginning with 1909 and professor of irrigation investigations and practice from 1928 till his retirement in 1935 on account of ill health, died September 17 at the age of 54 years. A native of California, he was graduated in civil engineering from the university in 1909 and received the C. E. degree from Stanford University in 1928. From 1908 to 1914 he was associated with the irrigation investigations of the U. S. Department of Agriculture, and in 1918 he served as first lieutenant of engineers in the U. S. Army.

Connecticut College and Storrs Station.—Leonard A. Salter, Jr., instructor and research assistant in agricultural economics, has resigned to become north-eastern regional chief of the Division of Land Economics, U. S. D. A. Bureau of Agricultural Economics. Dr. Dorothea Rudnick has succeeded Dr. Paul R. David, resigned, as research fellow in genetics. Laura Fasano and Margaret L. Cleveland have been appointed research assistants in animal diseases.

Delaware University and Station.—Dr. Paul L. Rice resigned as assistant entomologist September 1 to accept a position as head of the biology department of Alma College.

Florida University and Station.—Dr. F. B. Smith, associate professor and research associate in soils in the Iowa College and Station, has been appointed professor of soils and soil microbiologist. Dr. Edwin A. Ziegler has been appointed professor of forest economics, and P. W. Fraser and James W. Miller, Jr., assistant professors of forestry.

Hawaii University and Station.—John M. Westgate, in charge of the station from 1915 to 1935, and subsequently professor and consultant in tropical agriculture, died September 25 after an illness of several months. Born in Kingston, N. Y., on February 17, 1878, he was graduated from the Kansas College in 1897, received its M. S. degree in 1899, and pursued further graduate study at the University of Chicago from 1901 to 1903. He was assistant botanist from 1897 to 1901 at the Kansas College, assistant agrostologist in the U. S. D. A. Bureau of Plant Industry from 1903 to 1905, and in charge of the Department's alfalfa and clover investigations until 1914.

As head of the station and agronomist, Director Westgate made a notable contribution to the agricultural development of Hawaii, especially along the lines of increased diversification. He also took much interest in the sociological problems of the Territory and did much to promote American ideals among the many young men of oriental parentage with whom he came in contact in station and university work. In these and other ways he exercised a wide influence.

Iowa College and Station.—Dr. Paul Emerson, assistant and associate professor of soils from 1909 to 1932 and subsequently a senior soil scientist in the U. S. D. A. Soil Conservation Service, died in a South Dakota canyon September 20 from the effects of a rattlesnake bite. Born in Wilmington, Del., July 6, 1887, he received from the Delaware University the B. S. and M. S. degrees in 1914 and 1915 and from the Iowa College the Ph. D. degree in 1917. He had also served as soil bacteriologist in the Maryland and Idaho Stations.

Kansas College and Station.—The resignations are noted of Dr. A. C. Fay, professor of bacteriology and dairy bacteriologist, W. B. Balch, associate

professor of horticulture, and Dr. J. F. Knappenberger as instructor in bacteriology and poultry bacteriologist, all to engage in commercial work; Dr. J. P. Scott as professor of animal pathology to accept a position in the University of Pennsylvania; Dr. C. L. Lefebvre as assistant professor of botany and plant pathologist; and Esther Bruner Nelson as assistant professor in clothing and assistant investigator in textiles. They have been succeeded, respectively, by Dr. F. E. Nelson, instructor and assistant in dairy husbandry in the Minnesota University and Station; S. W. Decker, associate in fruit and vegetable marketing in the Illinois Station; Dr. Marvin J. Twiehaus; Dr. W. W. Thompson; Dr. D. B. Creager; and Dr. Hazel M. Fletcher. C. W. Mullen, associate editor of *Oklahoma Farmer-Stockman*, has been appointed assistant to the director and associate professor of agronomy.

Louisiana University.—N. D. Morgan has been appointed to succeed R. E. Wright as assistant horticulturist in the North Louisiana Station, effective January 1, 1938. Under an enlarged program, Dawson M. Johns has been appointed assistant in forage crops at the Northeast Louisiana Station, effective February 1, 1938.

Maine University.—Edson Forbes Hitchings, from 1905 to 1911 State entomologist and then till his resignation in 1917 associate professor of horticulture, died September 8, aged 84 years. He was a graduate of the college in 1875 and received the M. S. degree in 1888.

Minnesota University and Station.—Dr. W. M. Myers has resigned as instructor and assistant in agronomy and plant genetics to become associated with the regional pasture research laboratory at the Pennsylvania College. Dr. G. A. Swanson has been appointed in charge of teaching and research in wildlife and game management.

Missouri Station.—The last session of the legislature appropriated \$14,800 for horticultural experiment field work. Fields have been established in southeast Missouri near Campbell and Charleston, in southwest Missouri near Monett, and in central Missouri near Orrick. The purpose of these fields is to assist producers of fruits, vegetables, and truck crops in the solution of their cultural, harvesting, and handling problems in localities where these crops can be and are being grown extensively.

A rapid soil test perfected by the station was used during the past summer on a specially equipped train which made stops in 11 counties. About 1,000 samples of soil were submitted by farmers and tested for available phosphorus, potash, and calcium and the degree of acidity. Tests to ascertain the need of the soil for lime and phosphates and its supply of organic matter are also being made free of charge on samples sent in by residents of the State.

Montana College and Station.—The resignations are noted of Dr. A. H. Walker as assistant animal husbandman to accept a similar position in the Arizona University and Station and Kenneth J. Goering as assistant in chemistry. Effective September 1 Dr. E. J. Wellhausen has been appointed associate agronomist, Stanley B. Speck assistant in chemistry, Theodore I. Hedrick instructor in dairy industry, and Ruth M. Spick assistant in home economics research.

New Mexico College and Station.—K. W. Parker and Dr. K. W. Smith, assistant professors of animal husbandry and assistant animal husbandmen, resigned August 15 and September 1, respectively, and have been succeeded by J. O. Bridges and Dr. J. W. Benner. T. R. Timm, assistant agricultural economist in the station, was transferred August 1 to the position of agricultural economist in the extension division of the college and has been succeeded by R. L. Melcher.

Cornell University and Station.—A farm of 100 acres adjacent to the campus has been purchased to extend the program of the physiological field station on experimentally produced nervous disorders in animals under controlled conditions. A supply of pedigreed pigs, sheep, and other animals will be built up to provide breeds of diverse temperaments, and the behavior of the animals studied from birth to death in an attempt to clarify the understanding of experimental neuroses.

Dr. Peter W. Claassen, professor of biology and entomologist since 1926 and a leading authority on the Plecoptera, died August 16, aged 51 years. A native of Kansas, he received from the University of Kansas the A. B. degree in 1913 and the A. M. degree in 1915, as well as the Ph. D. degree from Cornell in 1918. He served as assistant State entomologist in Kansas from 1913 to 1915, then as instructor in biology in Cornell and assistant professor of entomology in the University of Kansas. He returned to Cornell in 1918 for continuous service thereafter except for a period in 1924-25 as a member of the faculty of Tsing Hua University in Peiping, China.

New York State Station.—L. M. Cooley, associate in research (plant pathology), has resigned to engage in farming in Ohio.

Pennsylvania College.—Edward B. Fitts, professor of dairy husbandry extension since 1922, died September 27, aged 67 years. He was a graduate of the Connecticut College in 1893 and had served as assistant in the Storrs Station and instructor in the college, as well as in the Louisiana Station, and from 1913 to 1922 was professor of dairy husbandry extension in the Oregon College.

Virginia Station.—Dr. L. E. Starr, associate animal pathologist, resigned August 31 to accept a position in the Alabama Polytechnic Institute, and was succeeded on September 20 by Dr. J. W. Scales. Other appointments include Dr. Mildred T. Tate and Gladys T. Stevenson as associate home economists and Mary C. McBryde as assistant in plant pathology, all effective September 1, and C. M. Kincaid as assistant animal husbandman.

Virginia Truck Station.—Dr. Jackson B. Hester, soil technologist, resigned effective September 1. Robert Oliver has been appointed assistant horticulturist.

Washington College and Station.—Otto Johnson has been succeeded by A. M. Neubert as assistant chemist. Dr. Victor Helman, assistant poultry husbandman, has resigned to carry on research in poultry and dairy feeds in New York, and Evelyn H. Roberts as research specialist in home economics to conduct tests of electrical appliances in Chicago. Recent appointments include R. D. Eichmann as assistant entomologist to work with insect problems of truck and greenhouse crops; Dr. Carl F. Reuss as assistant rural sociologist; Ruth C. Robbins as nutrition chemist; Dr. Leo Campbell as research assistant in plant pathology to work with diseases of sugar beets, vegetable, berry, and seed crops; Laraine E. Dunn as assistant in soils in connection with a State-wide project on fertilizers and problems of greenhouse soils; Wilford Hermann as assistant in farm crops; and Emmett I. Robertson as assistant poultry husbandman.

Wyoming University and Station.—Dr. R. S. Justice, assistant pharmacologist, resigned September 1 to accept a position in the University of Georgia. Alexander Johnston has been appointed assistant wool specialist for research and service work. Edward J. Talbot, instructor in marketing, will devote half time to research in the station as assistant economist.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R." to those of the experiment stations in Hawaii and Puerto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

Abortion—see also *Brucella abortus*.

- control, 689; Tenn. 391.
 - copulation infection among cattle, 541.
 - diagnosis, double intradermal test for, 699.
 - diagnosis, significance of suspicious agglutination reactions, 698.
 - eradication, cooperative work in, Wyo. 101.
 - immunity through natural exposure, transitory nature, Utah 101.
 - immunization studies, Ind. 391.
 - in cattle and hogs, agglutination tests for, Ind. 391.
 - in elk, tube and plate methods of testing, comparison, 399.
 - in ewes, 250, 849.
 - in guinea pigs, characteristic organism, Ind. 390.
 - in mares, 849.
 - in mares, differential diagnosis, 102.
 - in mares, epizootic or virus, Ky. 848.
 - in swine, control, Ill. 390.
 - in swine due to *Brucella abortus suis*, 849.
 - prevention, vaccination with live culture, 397.
 - reactors, failure to transmit the disease to susceptible animals, Wis. 538.
 - studies, 107, 244; [Conn.] Storrs 538.
 - trichomonad, in cattle, 398.
- Acanthocephala* sp., notes, Fla. 65.
- Accountancy, farm, see Farm accountancy.
- Accounts, home, aid to family saving and spending, Ill. 430.
- Acemyia callosi* n.sp., description, 370.
- Acetylene exploder, automatic, for protecting cherries from birds, Mich. 656.
- Acetylmethylcarbinol—
- and diacetyl, importance in butter cultures, Iowa 236.
 - fate in dairy products, 241.
 - oxidation to diacetyl in butter cultures, action of air under pressure in, 535.
 - plus diacetyl in butter, changes in, Iowa 536.
- Acidophilus milk, use in ice cream manufacture, Ill. 383.

Acids—

- amino, see Amino acids.
 - fatty, see Fatty acids.
- Acreage surveys, studies, U.S.D.A. 115.
- Acridium aegyptium*, parasites of, 370.
- Acrobeles*—
- bodenheimeri* n.sp., description, 808.
 - bütschlii*, role in cotton damping-off or soreshin, 348.
 - crossotus*, notes, 808.
 - variabilis* n.sp., description, 808.
- Acroceroops cramerella*, notes, 366.
- Actinolaimus*, feeding on other nematodes, 65.
- Actinomyces*—
- isolates, separation from scabbed potatoes and soil, 198.
 - scabies, antagonistic action of *Trichoderma* on, 795.
- Actinomycetes, acid-fast, from soil, pathogenicity for animals, 538.
- Adelges*—
- abietis*, studies, 659.
 - cooleyi*, life cycle in Britain, 72.
- Adrenal gland extract, cause of luteinization of ovaries and endometrial hyperplasia, 470.
- Adrenaline, effect on urinary excretion of vitamin C in rats, 138.
- Aedes taeniorhynchus*, transmission of western type of equine encephalomyelitis, 702.
- Acrobacter aerogenes*, effect of bile and bile salts, Mass. 739.
- Agalliopsis* leafhoppers, United States forms, food plants, 513.
- Agar—
- nutrient, pH of, methods of determining, 689.
 - plates, apparatus for pouring and washing, 196.

- smothering effect of ice sheets, Wis. 474.

Alfalfa—Continued.

- sod, fitting for wheat, Ohio 615.
- stem nematodes, studies, Okla. 58.
- substitution for part of clover in seed mixtures, Ind. 325.
- sweetclover, and Sudan grass pasture, comparison, S.Dak. 91.
- treatment with gypsum, Idaho 770.
- v. native meadow hay for milking cows, Wyo. 91.
- v. soybean hay for layers, feeding methods, Ohio 674.
- variety tests, Fla. 37; Idaho 770; Ill. 324; Iowa 180; Mass. 771; N.Mex. 181; Nebr. 614; Okla. 38; Pa. 39; S.C. 39; U.S.D.A. 182; Utah 40; Wash. 325; Wyo. 40.
- vitamin A in, Tenn. 418.
- webworm, control, Ill. 359.
- weevil, studies, Nebr. 657.
- wilt-resistant varieties, improved, development, Wis. 474.
- winter hardiness in, cytology and physiology, Iowa 180.
- winter-hardy varieties, improved, development, Wis. 474.
- yellowing due to boron deficiency, 797.
- yields, U.S.D.A. 773.
- yields in Hawaii, effect of frequency of cutting, 618.
- yields on silt loam soils, increasing, Wis. 448.

Algae—

- death due to light and resistance to strong light in assimilatory tissues, 761.
- nitrite and formaldehyde formation in, 172.
- nitrogen-fixing, physiological studies, 602.

Allitoxicoxis, cause, 891.

Akkuraks new genus, erection, 662.

Alkali—

- disease in hogs from corn grown in selenium-containing area, 251.
- disease or selenium poisoning, S.Dak. 100.
- land, treatment, Utah 13.
- soils of Iowa, Iowa 158.
- soils, types, 306.

Allelomorphs, agouti and albino series, description, 318.

Almond oil, vitamin B₁ in, 135.Alopecurus pratensis, damage by *Apamea secalis*, 72.

Alpine rock crawler, control, Mont. 66.

Alternaria—

- dianthi*, notes, Mass. 795.
- spot of cotton, P.R.Col. 795.
- tenuis* on tobacco, Conn.[New Haven] 351.

Aluminum—

- salts, use to combat effect of fluorine in diet, Wis. 562.
- toxicity of acid soils, phosphorus and lime for reducing, 315.

Amaryllis hybrid, pollen longevity, 490.

American Dairy Science Association, proceedings, 332.

Amides, metabolism in tobacco leaves, Conn. [New Haven] 580.

Amidostomum anseris in wild waterfowl, 549.

Amino acids, dicarboxylic, isolating from products of protein hydrolysis, Conn.[New Haven] 580.

p-Aminobenzenesulfonamide—

- efficacy in pneumococcal infections of rats, 540.

- mode of action in hemolytic streptococcal infections, 396, 849.

Ammonium bicarbonate, substitution for oil cake protein for cows on beet silage, 237.

Ammonium chloride administration, effect on ascorbic acid in urine, 282.

Amoebiasis in rats with cysts of human carriers, 245.

Amphicooma vulpina on cranberry, Mass. 815.*Amphorophora rubi*, notes, 787.

Amylase in milk, 240.

Anabrus simplex, see Cricket, Mormon.*Anacamptis fragariella* parasites, 359.

Anaerobes, treatise, 694.

Anaesthesia, epidural, and anatomy, correlation in domestic animals, 243.

Anagyrus—

- coccidivorus*, parasite of pineapple mealybug, importation and breeding, 373.

- iliacini*, parasite of coffee mealybug, 818.

Anaplasma—

- centrale* and *marginale*, cross-immunity tests, 699.

- marginale* and *centrale*, cross-immunity tests, 699.

- marginale*, exposure to different degrees of temperature, 245.

- marginale*, notes 699.

Anaplasmosis—

- bovine, etiological agent, effect of exposure to different degrees of temperature, 699.

- cases in Oregon, 246.

- in cattle, 541.

- in Idaho, 106.

- transmission, new facts, Okla. 66.

Anasa—

- armigera*, notes, Conn.[New Haven] 813.

- repetita*, notes, Conn.[New Haven] 813.

- tristis*, see Squash bug.

Anacylis comptans, see Strawberry leaf roller.

Anemia—

- and rickets, relation, Wis. 562.

- effect on rate of fat absorption in rats, 422.

- in children, relation to iron of home-grown foods, Fla. 128.

- nutritional, effect of raw v. pasteurized milk, correction, 92.

- treatment, need of copper as iron supplement, Wis. 562.

Angoumois grain moth, mass production, 670.

- Anguillulina*—
dipsaci on sweetpotatoes, 800.
pratensis, relation to root injury of fruit trees, 61.
- Anguina spermophaga* n.sp., seed parasite of *Saccharum spontaneum*, 808.
- Animal—
 and plant nutrition, treatise, 878.
 breeding—see also Breeding, Hybridization, and specific animals.
 for increased efficiency, 466.
 fundamentals, 672.
 plans, 468.
 plans, treatise, 227.
 selective, reduction of high mortality by, Idaho 848.
 byproducts, value in dairy ration, N.J. 582.
 census of two pastures and a meadow in northern New York, 653.
 chromosomes, see Chromosomes.
 diseases—see also specific diseases.
 and parasites, [Conn.] Storrs 537.
 and parasites in Madras, 108.
 control, 105.
 diagnoses, results, Ind. 391.
 in Cyprus, 244.
 in New Zealand, 244.
 in Trinidad and Tobago, 101.
 internal, clinical diagnosis, treatise, 694.
 fats, see Fats.
 geography, ecological, 808.
 husbandry, Kellogg Institute of, 672.
 hybrids, sterility of, problem, 467.
 life, relation to land and water resources, U.S.D.A. 707.
 parasites, see Parasites.

- Anyphus orientalis*, notes, 671.
- Apamea secalis*, distribution, life history, and economic importance, 72.
- Apanteles* sp., notes, 821.
- Aphelenchoides*—
 feeding on other nematodes, 65.
limberi n.sp., description, 808.
parietinus, role in cotton damping-off or soreshin, 348.
ribes, control, 219.
- Aphelenchus avenae*, role in cotton damping-off or soreshin, 348.
- Aphelinus mali* as parasite of woolly apple aphid, value, 219.
- Aphid, yellow, of sugarcane, biology and control, 515.
- Aphidae of Colorado, additions and corrections, 513.
- Aphididae, new California, description, 221.
- Aphids—
 artificial feeding, improved device for, 65.
 damage to peas and tomatoes even after nicotine sulfate sprays were used, R.I. 814.
 Florida, biology and control, Fla. 65.
 in orchards, dormant treatment for, Ky. 814.
 rabbit brush and willow, new, descriptions, 513.
 reaction to colored insecticides, 364.
 woolly, see Apple aphid, woolly.

Aphis—

- abietina*, see Spruce aphid.
- gossypii*, see Cotton aphid and Melon aphid.
- maidis*, see Corn leaf aphid.
- medicaginis*, see Cowpea aphid.
- pomi*, see Apple aphid.

Apiaries, inspection, Conn.[New Haven] 813.
Apiculture, see Beekeeping.

Apioportha associated with tree canker, 637.
Aplanobacter stewartii bacteriophage, inhibiting, Ohio 637.

Apophallus venustus, life history and bionomics, 656.

Apparatus—

- for constant temperature, 764.
- for continuous measurement of photosynthesis, respiration, and transpiration, 457.
- for fumigation with low concentrations of nicotine, 812.
- for measurement of plant respiration, 174.
- for measurement of serum pH, 540.
- for measurement of shrinkage coefficient of soils, 15.
- for measuring leaf areas, Pa. 26.
- for mixing insecticidal dusts, U.S.D.A. 216.
- for recording time and duration of rainfall, 155.
- for sampling of Florida sands, 591.
- for separating insects and other arthropods from soil, 357.
- for softening wood for microscopic sections, 764.
- for treating plants with heat, 31.
- new shear, for determining shearing resistance of fill materials, 404.
- semi-micro-Cottrell boiling point, 6.
- torsion pendulum, for determining viscosity of eggs, 685.
- used in farm structures research, 259.

Appendicitis, hemorrhagic, among poultry, brachylaemi as cause, 703.

Apple

- aphid, control in Ohio, 663.
- aphid, field tests of new aphicides for 658.
- aphid, rosy, control, 663; Conn.[New Haven] 813.
- aphid, woolly, increase in parasite control, Idaho 813.

keeping quality in storage, short-time holding test for, S.Dak. 844.

lactic acid in, determination, [N.Y.] Cornell 442.

lipolytic and proteolytic micro-organisms in, relation, S.Dak. 91.

manufacture, trends in, 92.

mold in, methods for estimation, 745.

quality, effect of soybean feeding, 389.

quality, relation to amino nitrogen in, S.Dak. 91.

rancidity in, cause, Iowa 236.

scoring work at State College of Washington, 92.

standardization, value of graphic chart, 92.

storage in wood containers, tests for odor and flavor, U.S.D.A. 97.

surface taint in, micro-organisms causing, Iowa 236.

vitamin A value, effect of soybean feeding, 388; Ind. 383.

wintery flavor in, relation to bacteria and enzymes, Idaho 839.

yeast and mold counts in, relation to churn cleaning methods, 242.

Butterfat—

Babcock test for, standard methods, Ky. 95.

in milk, effect of feeding menhaden oil, Ohio 637.

loss in churning, factors affecting, 96, 844.

of maximum vitamin A value, Ind. 383.

oxidation, 692.

percentage of first lactation and subsequent lactations, 844.

price paid to producers for, economic aspects, Okla. 807.

produced on begari fodder and cottonseed meal, vitamin A content, N.Mex. 236.

production in first five lactations, relation to age at first calving, 672.

Reichert-Meissl and iodine values, effect of feeding alfalfa hay, Idaho 839.

stability toward oxidation, factors affecting, Wis. 533.

tests, specifications for Babcock glassware, Md. 242.

tests, variation in, cause, N.Y.State 242.

transition point, 241.

vitamin A activity, 97.

vitamin A value, relation to carotene content, Ind. 383.

Buttermilk—

fat determination in, Minnesota reagents for, 7.

fat losses in, effect of acidity in cream, Iowa 235.

fat losses in, effect of neutralizers, Iowa 236.

for fattening bacon pigs, 379.

n-Butyric acid, production from sugarcane final molasses, P.R.Col. 739.

Cabbage—

aphid, notes, 801; Tenn. 380.
arsenical dusting, relation to poison residues, U.S.D.A. 217.
breeding, S.C. 44.
clubroot, notes, N.J. 493.
diseases, control, Wis. 493.
diseases in New York, U.S.D.A. 636.
early, tests, Tenn. 333.
fertilizer requirements, Fla. 43; S.C. 44.
looper, control, Ohio 658; Va.Truck 819.
looper, pyrethrum as insecticide for, 365.
maggot, control, calomel dust v. corrosive sublimate, R.I. 814.
maggot, control with mercury compounds, Mass. 814.
mosaic, increasing importance, 198.
sick soils, substitute crops for, Iowa 186.
summary of studies, La. 624.
varieties grown in England, classification, 482.
variety tests, Pa. 44; R.I. 783.
vitamin C in, 280.
winter, improvement, Pa. 44.
yellows-resistant, Conn.[New Haven] 636.

Cabbageworm, imported, control, Ohio 658; Va.Truck 819.

Cabinet for control of humidity and temperature for agronomic experiments, 473.

Cacao—

fertilizer experiments, 488.
pod borer moth, notes, 366.

Cacoeia argyrosipila, see Fruit tree leaf roller.

Cake—

bread, and pastry, homemade, recipes, U.S.D.A. 882.
flours, testing, sugar tolerance in A.A. C.C. basic formula, 129.
honey in, 724.
making, relative merits of beater and whip and of size of mixing bowl, 129.
making, sugar and shortening tolerance of soft wheat flour for, 129.

Calcium—

arsenate—

commercial, analyses, 509.
experiments for codling moth control, 367.
particle size, by sedimentation analysis, 509.
stickers used with, 509.
studies, 68.

cyanamide, effect on soil microflora, 310.

deficiency for New Zealand livestock, 377.

effect on germination of seed of *Hypericum perforatum*, 29.

in blood serum of horses, variations in, 545.

in body, relation to calcium and phosphorus of food, 727.

Calcium—Continued.

in diet, relation to rate of healing of experimental fractures in rats, 275.

in forage plants, effect of magnesic liming materials, R.I. 749.

in grazing forages, N.Mex. 228, 522.

in mineral mixtures, conformation to experimental findings, 673.

in pasture herbage, effect of fertilization and liming, 776.

in poultry ration, effect on egg production and hatchability, 530.

in semen, blood serum, and secretions of sexual glands, 323.

metabolism and therapy, 244.

metaphosphate, new, Tenn. 302.

phosphate, glassy, new type, studies, Tenn. 302.

proteinate, ionization constants, 9.

requirements of lambs, Ohio 674.

role in crop production, 166.

sources, relative efficiency for fattening pigs, Iowa 227.

state and partition in serum of fowls, 88.

supplements for pigs, Ill. 678.

Calendula, *Cercospora* leaf spot of, 197.

California Station, notes, 143, 895.

California University, notes, 143, 895.

Callimome druparum, see Apple seed chalcid.

Calliphora erythrocephala fed on fatigued frog muscle, growth stimulation, 223.

Callirhipis—

incerta n.sp., notes, 216.

robusta indica n.ssp., notes, 216.

Callosobruchus maculatus, see Cowpea weevil.

Calomycterus setatus, notes, Conn.[New Haven] 813.

Calves—

beef, creep-feeding, S.C. 79.

beef, fattening, comparison of feeds before and after weaning, U.S.D.A. 524.

beef, fattening, dry lot v. pasture, Ill. 374.

black-spotted lowland breed, congenital hairlessness in, 177.

creep-fed v. noncreep-fed, finishing, Okla. 78.

dairy, bone studies, Ohio 687.

dairy, feeding limited quantities of whole milk, 840.

dairy, raising, effect of dry rations, Wis. 532.

effect of feeding poor quality hay, Pa. 90.

fattening, Ind. 374.

fattening, protein supplement in, 672.

fattening, wheat bran v. oats with barley for, Idaho 826.

feeder, wintering, Ga.Coastal Plain 78.

feeding vitamin A and D concentrate in cod-liver oil, N.Y.State 237.

mortality in Iowa State College herd, 673.

newborn, changes in weight, relation to feeding method, 384.

Calves—Continued.

- on bluegrass pasture, corn supplements for, Ohio 523.
- on pasture, addition of protein supplement to full feed of corn for, Ohio 674.
- raising, Mo. 238.
- raising on wire floors, N.J. 525.
- raw v. pasteurized milk for, 689.

- juices, vitamin C in, 731.
- leaf sap, osmotic value, cryoscopic determination, 488.
- leaves and fruits, potassium in, 633.
- leaves, fumigated, recovery of hydrocyanic acid from, 6.
- leaves, mesophyll collapse, 62.
- maturity studies, Fla. 43.
- melanose, control, Fla. 54.
- mottle leaf, effect on fruit size, 805.
- mushroom root rot, Fla. 54.
- nitrogen fertilization and root aeration, 788.
- phosphorus in, factors affecting, 632.
- progeny and bud selection, Fla. 43.
- propagation and testing new varieties and hybrids, Fla. 43.
- psorosis, bark symptoms, similarity to boron-deficiency effects, 504.
- psorosis in Florida, 805.
- rootstock and scion effect, 103.
- rootstocks for, P.R. 783.
- scab, control, Fla. 54.
- species, colorimetric tests for, 480.
- stem-end rot, control, Fla. 53, 54.

Citrus—Continued.

- trees, disease-free, aim of experiment station, 804.
- trees, frozen, effects of whitewashing, 489.
- trees, gummosis and psorosis of, new aspects, 354.

Cladosporium—

- leaf disease of snapdragons, U.S.D.A. 403.
- paeoniae*, cause of peony leaf blotch, 350.
- Clasterosporium carpophilum*, notes, 61.

Clay—

- adobe, Gila, colloids, effects of irrigation and cropping, N.Mex. 158.
- forest soils, contrasting, studies, 50.
- minerals, composition and crystal structure, 303.
- pots, moist mats for, Mass. 782.
- products, use in farm building construction, Iowa 255.
- soils, drainage experiments, 164.
- soils, phosphate fertilizer for, Ind. 302.
- soils, Wabash, utilization in crop production, Mo. 615.

Clemson College, notes, 143.

Clensel bait tests against Mediterranean fruitfly, 371.

Climate—see also Meteorology.

- and insects, studies, N.J. 506.
- changes in, 11.
- climax, and succession, 166.
- in southern New England and adjacent New York, recent changes, 747.
- rainfall, and soil humidity from agromomic standpoint, 156.

Climatic—

- changes in present time, teleconnections, 301.
- cycles, 746.
- zones of Montana, Mont. 774.

Climatological—

- data, U.S.D.A. 10, 300, 746, 748.
- research, 166.
- summary for 1935, Ohio 587.

Clitica metallica, notes, 372.*Clostridium*—

- chauvei*, role in blackleg, 246.
- histolyticus* infection in horses, 103.
- n.spp. capable of fermenting sulfite waste liquor, 591.
- oedematiens*, control with copper sulfate, 106.
- oedematiens* toxoid, antigenic value, determination, 700.
- tetrum* n.sp., description, 602.
- welchii* group and infectious enterotoxemia, 399.
- welchii* in a pack of commercially canned roast beef, 563.
- welchii*, type B, antitoxins for, efficiency, 250.

Cloth tents, effect on growth of flowering plants, Ohio 684.

Clothes moth, webbing, casebearing, 218.

Clothes moths, preventing injury and destroying the insect, Ill. 659.

Clothing, protection in storage by insecticides, Ill. 360.

Clover—

- alsike, effect of cutting at different times, Iowa 180.
- anthracnose in Wisconsin, U.S.D.A. 636.
- bur, diseases in Georgia, U.S.D.A. 343.
- crimson, seed treatments and seeding tests, Tenn. 325.
- culture experiments, Idaho 770.
- digestible nutrients under different methods of conservation, 228.
- failure, relation to pea aphid, Ky. 814.
- hay, producing, baling, and loading for market, U.S.D.A. 474.
- Ladino, breeding experiments, Idaho 770.
- leaf spot disease, 498.
- leaf weevil parasite in United States, 359.
- nodule producing organism, effectiveness, effect of host plant species, 172.
- red, anthracnose-resistant, Tenn. 343.
- red, brooding, Ky. 771.
- red, chemical composition, Ky. 827.
- red, culture experiments, Ill. 324.
- red, effect of cutting at different times, Iowa 180.
- red, failure, relation to soil productivity and diseases, Ky. 794.
- red, foreign strains, adaptability, Ill. 616.
- red, fresh and dried roots and shoots, hydration studies, 313.
- red, nurse crop and cutting tests, Ill. 324.
- red, soil acidity tolerance, Pa. 39.
- red, variety tests, Ill. 324; Iowa 180; Ky. 771; Tenn. 325; Wash. 325.
- strawberry, culture experiments, Wash. 325.
- strawberry, for western alkali lands, Utah 13.
- sweet, see Sweetclover.
- varieties, adaptability for pastures, [Con.] Storrs 473.
- variety tests, Okla. 38.
- white, variety tests, Ky. 771.

Club work, see 4-H club.

Clutocycba tabescens, notes, Fla. 54.

Coal ashes, German brown, rare elements in, 454.

Coal tar distillates, extended insecticidal uses, 359.

Cobalt—

- deficiency for New Zealand livestock, 377.
- feeding to rats, effect, 675.
- importance in treatment of livestock ailments, 391.

Coccidia, infection, effect of diet on severity, 695.

Coccidioidal granuloma of cattle, pulmonary lesions in, 852.

Coccidiosis—

- avian, immunity experiments, Ohio 603.
- avian, oocyst production in, 858.

Coccidiosis—Continued.

- avian, prevention and treatment, 849.
- in chickens, use of sulfur in, Wis. 546.
- in poultry and other fowl, Mo. 99.
- nature and etiology, 107.
- prevention with sulfur, Wis. 538.
- studies, [Conn.] Storrs 538.

Cochliomyia americana, see Screwworm.

Cochlonema n. sp., description, 345.

Cocker spaniel, albinism in, 608.

Cockroach, American, penetration of arsenical compounds into body, 360.

Cocks in Denmark, keeping of pedigree registers for, 680.

Cocoa husks as feeding stuff, 828.

Coconut—

- leaf-mining beetle and its parasites, biological control, 822.

- oil, effect on quality and palatability of beef, Iowa 228.

- scale, effective predators, introduction from Trinidad, P.R. 509.

- thrips parasite, introduction from Trinidad, P.R. 509.

Coconuts, culture, P.R. Col. 783.

Codfish meal, preparation and biological value, 223.

Codling moth—

- activity, Wash. 221, 361.

- bait trap records, 360.

- bait trapping, Tenn. 361.

- banding for, 658, 664.

- bands, chemically treated, preparation of trees and application, Mich. 665.

- biometrics and control, Del. 215; Iowa 215.

- control, 510, 658; Mont. 66; Wash. 361.
- control, adjusting spray program for, 664.

- control and orchard sanitation, 658.

- control in Washington, recommendations for, 658.

- control, recent developments in Pacific Northwest, 658.

- control, toxicity of nicotine combinations, Mich. 366.

- control, types of lead arsenate and fish oil soap for, Md. 664.

- control with calcium arsenate, 367.

- control with cryolite, tests, 819.

- control with lead arsenate substitutes, 72.

- dates for cover spray applications, early determination, Utah 67.

- diapause, experimental break, 367.

- eggs, hatching, new technic, 507.

- experimental spray program, Ohio 658.

- increase in parasite control, Idaho 813.

- infestation, effects of light traps, 515.
- insecticide and trapping experiments, N.Mex. 215.

- larvae, methyl bromide fumigation, 850.

- larvae, parasitism by native parasites in Georgia, 812.

- lead arsenate sprays for, stickers and spreaders used in, 509.

- new insecticides for, tests, 658.

Codling moth—Continued.

- parasite, laboratory breeding in British Columbia, 227.

- populations, effect on control experiments, 360.

- spray schedules, effect on other orchard insects, 510.

- spraying results, 658.

- studies, Ind. 360; Nebr. 657; Pa. 67.

- survey, 658.

- traps, bait and light tests, 515.

Cod-liver oil—

- normal and concentrated, calcifying property, effect of charcoal and length of storage on, 684.

- subcutaneous injection, tissue response, 279.

- v. ultraviolet irradiation as sources of vitamin D for confined laying hens, 528.

- vitamin A and D concentrate, value in calf ration, N.Y. State 237.

Coffee—

- and decaffeinated coffee, effect of oxygen consumption, pulse rate, and blood pressure, 132.

- farms, management studies, P.R. Col. 261.

- fertilizer and shading requirements and varieties, P.R. Col. 782.

- groves, insects as pollinating agents, P.R. Col. 814.

- leaf miner, parasitism, P.R. Col. 814.

- production and consumption, world problem, 263.

Coleophora prunella, see Cherry casebearer.

Coleoptera—

- Indian, immature stages, 216.
- of an original prairie area in Nebraska, 223.

- of Utah, distribution, 223.

Coli-aerogenes group—

- action on erythrosin, Mass. 739.
- in milk, detection and significance, 690, 691.

- presumptive test media, comparison, Pa. 100.

- tolerance for brilliant green, Mass. 739.

Collards, summary of studies, La. 624.

Collective bargaining, proposed, for French agricultural workers, U.S.D.A. 117.

College freshmen, increase in height and weight and decrease in age in twenty years, 420.

Colletotrichum—

- falcatum*, notes, 643.

- lagenarium* on watermelon, biology and control, Iowa 199.

Colloids—

- of Gila clay adobe, effects of irrigation and cropping, N.Mex. 158.

- removal from soil samples, Wis. 448.
- soil, chemical and physical changes in, 17.

- soil, crystallinity, evidence of, 305.
- soil, heat of wetting at different moisture contents, 450.

- soil, relation to crystal structure, 304.

Color—

- genes, action in guinea pigs, 466.
- inheritance in hunting dogs, 35.
- inheritance in swine, 177.

Colostrum—

- human, vitamin A and carotenoid in, 423.
- of first-calf heifers, streptococci in, 103.

Colts, production, Iowa 228.

Combines—

- harvesting costs, 712.
- harvesting with, Ill. 403; Ind. 403; Ohio 707.
- small, use, Ind. 410; Mich. 408.
- utilization and cost of harvesting small grains with, U.S.D.A. 406.

Community buildings, rural, planning and financing, Ill. 561.

Composts, organic matter in, chemical nature, 450.

Compsilura concinnata, laboratory propagation, 74.*Comys infelix*, biology and relations with host, 359.

Concrete—

- test specimens containing burnt clay aggregates, strength, effect of curing conditions, U.S.D.A. 530.
- use on the farm, U.S.D.A. 865.

Coniferous seedlings, damping-off, Iowa 200

Conifers—

- damping-off control, 198.
- development in raw humus, 635.
- in Hudson Highlands, terminal growth, 51.

Coniothyrium species on strawberry roots, 354.

Conjunctivitis, contagious, of sheep in Algeria, 854.

Connecticut—

- College, notes, 736.
- [New Haven] Station, report, 735.
- State Station, notes, 432, 736.
- Storrs Station, notes, 895.
- Storrs Station, report, 575.

Conocephalus saltator, notes, Hawaii 90.*Conotrachelus nemophar*, see *Plum curculio*.

Consumers' cooperation in world, 876.

Cooking utensils—

- application of heat from electric surface units to, Iowa 286.
- cost of using on electric heating units, Me. 735.

Cooperation, see Agricultural cooperation.

Cooperative—

- enterprises, possibilities of cutting profit margin through, Okla. 116.
- organizations, agricultural, in California, Calif. 123.

Copper—

- absorption by food plants, Mass. 771.
- action on formation and color of conidium of *Aspergillus* spp., 757.
- and iron in metabolism, 133.
- and zinc, comparative nutritive effects, Mass. 748.
- ascorbic acid oxidase in relation to, 584.

Copper—Continued.

- containing spray materials, effectiveness for vegetables, Ohio 637.
- contamination during production and processing, relation to oxidized flavor development, 385.
- deficiency in sugar beets, 59.
- detection in alloys, 585.
- determination methods, Fla. 7.
- dusts, comparative effectiveness for celery leaf blights, Mich. 347.
- effect on growth of cranberry vines, Mass. 782.
- fungicides, tests, Ohio 637.
- in blood, relation to hemoglobin formation, Wis. 562.
- in human and animal tissues, 566.
- in milk, 690.
- in normal calf ration, Ohio 687.
- microdetermination, catalysis of oxidation of thiol acids as basis, 7.
- oxide, red, as rose spray, tests, 648.
- permanganate titration method for, 744.
- requirement of pigs, Ill. 374.
- role in crop production, 166.
- sprays for apple fire blight control, Wis. 493.
- sprays, new, for cherry leaf spot control, Mich. 333.

Corn—

- acres and yields, 1866-1935, Iowa 260.
- aleurone color in, effect of varying gene dosage, 175.
- and corn growing, treatise, 610.
- bacterial wilt, forecast of incidence, 199.
- bacterial wilt resistance, genetic studies, Iowa 200.
- bacterial wilt resistance to open-pollinated varieties, 204.
- black-bundle disease, relation to *Cephalosporium acremonium*, 204.
- black ear rot, 347.
- borer, European—
 - control, Conn.[New Haven] 657, 813.
 - control, insecticides for, Mass. 814.
 - egg and larval populations, relation to time of planting sweet corn, 368.
 - insecticides on early sweet corn for, Conn.[New Haven] 665.
 - reaction to light traps, 369.
 - resistance, Ohio 658.
 - resistance of hybrid strains of corn to, 368.
 - studies, Ill. 359; Ind. 360.
- breeding, Fla. 37; Idaho 770; Ill. 324; Ky. 771; La. 614; N.J. 473; Nehr. 614; Okla. 38; S.Dak. 39; Tenn. 325.
- Bt Pr linkage group, differential fertilization in, 33.
- byproducts, action of fungi on, fermentation products, Iowa 200.
- caryopsis in, developmental morphology, 183.

Corn—Continued.

characteristics as related to industrial use, Iowa 147.
 chemical composition, Ky. 827.
 chlorosis in, relation to chemical nature of culture solutions, 347.
 composition and strength of stalk, correlation, Iowa 181.
 cultivation experiments on sandy lands, Wis. 474.
 cultivators, types for seedbed preparation, Iowa 255.
 culture experiments, Fla. 38; Tenn. 325; Wyo. 40.
 curing and storage studies, Iowa 181.
 date of planting tests, La. 473; Mont. 326.
 dent, hardness, factor in nutritive value for fattening pigs, 672.
Diplodia dry rot, Iowa 200.
 diseases, Ind. 343.
 drying, artificial, Ill. 403.
 ear, in cribs, pressure and load exerted by, Ohio 707.
 ear rot fungi, prevalence and distribution, U.S.D.A. 636.
 ear rot, relation to ear coverage by husks, 797.
 ear rots at University of Illinois, U.S.D.A. 53.
 ear v. shelled, for spring pigs, Ind. 374.
 earworm—
 as pest of tomato, control, 665.
 control, N.Y. State 821.
 control, effectiveness of cultivation, U.S.D.A. 517.
 control, poison baits for, 73.
 cottonseed meal as bait, Tenn. 360.
 damage, relation to tightness of husk, Okla. 66.
 injury, reduction with cryolite, Idaho 818.
 moths, reaction to light traps, 360.
 new varieties of sweet corn resistant to, 188.
 resistance of corn hybrids to, Ill. 359.
 resistant varieties, 188.
 seasonal availability of food plants, 73.
 studies, Conn. [New Haven] 657; Ind. 360; Nebr. 657.
 effect of manure on nonirrigated crops, Wyo. 40.
 fed as silage and as corn-and-cob meal, acre returns from, Ohio 674.
 fertilizer experiments, Fla. 38; Ga. Coastal Plain 38; Ind. 325; La. 181, 614; Tenn. 325; Wash. 325.
 fodder and stover, whole and shredded grades, Iowa 181.
 fodder, yields, U.S.D.A. 773.
 for silage, yields, Wis. 474.
 futures, U.S.D.A. 718.
 genetic studies, Iowa 180.
 gluten meal proteins, value for lambs, 526.

Corn—Continued.

grains, sterilization with sodium hypochlorite, 641.
 green and chlorophyll-deficient, respiration, 598.
 growing, mechanized, 405.
 growing, tests of equipment for, Iowa 255.
 growth in tank cultures, Ohio 615.
 harvesting machinery, S.Dak. 109.
 hereditary differences affecting animal preference, Ill. 374.
 hill fertilization, Ohio 615.
 hybrid, experiments with, Ohio 615.
 hybrid, identifying color factors in, introduction, Wis. 474.
 hybrid, irregularly shaped kernels, mechanical equipment for planting, Ohio 706.
 hybrid, seed from, merits for planting, Wis. 473.
 hybrid strains, borer resistance in, 368.
 hybrids, resistant to ear rots, Ill. 324.
 hybrids, seed production and distribution, Iowa 181.
 improvement by topcrossing and reconstitution, Ill. 324.
 inbred, crossing plot for increasing seed, 606.
 inbred lines, progeny, cytological study, 605.
 inheritance and improvement studies, Wash. 325.
 interplanted with soybeans, La. 181, 614.
 interplanting with velvetbeans, Fla. 38.
 irrigation requirements, Utah 110.
 kernels, smooth v. rough, susceptibility to seed coat injury, Ill. 324.
 land, methods of preparing, U.S.D.A. 182.
 large amounts, use in laying rations, Ind. 375.
 leaf aphid, method for study, 358.
 nitrogen sources for top dressing, comparisons, La. 181.
 nutrition studies, N.J. 455.
 nutritive value for poultry breeds, 681.
 oats, and wheat, relative efficiency against gizzard lesions in chicks, Wis. 522.
 paradichlorobenzene-treated, effect of feeding to swine, 701.
 picker, mechanical, loss, Ind. 403.
 plant extracts, effect on growth of excised root tips, 170.
 plant, nutrition and development of desirable nutritional habits, Ill. 324.
 planting tests, Ind. 325.
 prices, factors affecting, Iowa 260.
 prices, regional differences, Tenn. 557.
 production—
 and marketing in British Empire, 415.
 in United States, Ill. 410.
 mechanical, Ind. 403.
 on Richfield silt loam soil. [Okla.] Panhandle 182.

Corn—Continued.

- production—continued.
 - under dry land farming, Mont. 326.
 - with mechanical power, Pa. 109.
- proteins, quality and quantity, Ind. 293.
- red, effect of colored cellophane on production, 598.
- residual effects of fertilizers and of cover cropping, R.I. 771.
- response to zinc, Fla. 38.
- root aphid, studies, S.C. 67.
- root growth, effect of different concentrations of heteroauxin on, 759.
- root tips, excised, growth, effect of extracts from corn plant, 170.
- root tips, excised, limited growth and abnormalities in, 27.
- root webworm affecting tobacco, improved poisoned bait for, 507.
- roots, toxicity in meristem cells, cytological studies, 599.
- rootworm, southern, and weedy corn, Ohio 658.
- rotation experiments, Fla. 38; La. 473.
- seed-borne plant pathogens, detection, Iowa 200.
- seed, chemical treatments, physiological response of plant and pathogen, Iowa 200.
- seed, disinfection with mercury dust, large-scale field trials, 57.
- seed driers, improvement in, Wis. 474.
- seed, effect of organic mercury dusts, Iowa 200.
- seed, germination, relation to ripening stages, 762.
- seed, hybrid, production on Nebraska farms, 614.
- seed, kernel characteristics, relation to yield, Iowa 181.
- seed, longevity, effect of luteus genes, 175.
- seed, protection from birds, Ohio, 658.
- seedbed preparation and planting, La. 181.
- seedlings, ethyl mercury phosphate poisoning in, 641.
- shelled, grades for, Wis. 474.
- shrinkage in storage, Ill. 324.
- silage, *see* Silage.
- smut resistant strains, factors affecting, Iowa 200.
- smut, susceptible varieties, 188.
- soft, storage and use, Ill. 370.
- spacing effects, 777.
- spacing tests, La. 181.
- stored, search for improved fumigant, Ill. 359.
- structure, effect of boron deficiency, 315.
- sweet, *see* Sweet corn.
- tillage experiments, U.S.D.A. 773.
- triploidy in, origin, 175.
- types for fattening pigs, Iowa 227.
- ultraviolet radiation in, genetic effects, 31.
- use in turkey rations, S.Dak. 79.
- v. molasses for yearling heifers, Nebr. 673.

Corn—Continued.

- value in poultry rations, S.Dak. 79.
 - varieties and hybrids, yields, 614.
 - varieties for livestock feed, Utah 40.
 - varieties, new or improved, seed increase, Iowa 181.
 - variety tests, Fla. 37; Ga.Coastal Plain 38; Ill. 324; Iowa 181; Ky. 771; La. 181, 473, 614; N.J. 473; N.Mex. 181; Nebr. 614; Okla. 38; S.C. 89; Tenn. 325; U.S.D.A. 182; Utah 40; Wash. 325; Wyo. 40.
 - vitamins in, effect of variety and growth stage, Mass. 879.
 - wilt resistance, correlation with lateness and height, Wis. 493.
 - winter cover crops for, Ga.Coastal Plain 38; La. 181.
 - yellow endosperm coloration in, gene producing, 35.
 - yellow varieties, vitamin A in, Ill. 419.
 - yield and time to first silks, analysis of covariance, 475.
 - yield, effect of age, size, and source of seed, Nebr. 476.
 - yield, effect of balancing plant food, Ill. 302.
 - yield, effect of color, Wis. 474.
 - yield, effect of crop rotations, Ohio 615.
 - yield, effect of tillage, Mont. 325.
 - yield in different sequences, U.S.D.A. 182.
 - yield in 4-yr. rotation, U.S.D.A. 182.
 - yield per acre, Ohio 711.
 - yield test of Iowa, Iowa 326.
 - yield, variation on limed and fertilized plats, Ohio 615.
- Cornell University, notes, 288, 897.
- Cornstalk—
- ash and residues, fertility value, Ill. 324.
 - borer, southern, S.C. 67.
 - borers, studies, Iowa 215.
 - carbohydrate constituents, water-soluble and acid hydrolyzable, identification, Iowa 147.
 - covering equipment, Ind. 403.
 - disease of horses, fatal, Ill. 390.
- Corticium* disease of turf, 197.
- Corynebacterium ovis* in deer, 854.
- Corythucha cydoniae* on *Cotonaster*, Ohio 658.
- Cosmopolites sordidus*, *see* Banana root borer.
- Cost of production, *see* specific crops.
- Cotinis nitida*, *see* June beetle, green.
- Cotonaster* webworm, life history, 73.
- Cotton—
- agreement, Japan-India, U.S.D.A. 712.
 - ammonia and nitrate nitrogen for, Ga. 328.
 - and linters, international trade in, U.S.D.A. 123.
 - anthracnose, varietal resistance, S.C. 54.
 - aphid, studies, Ohio 658; S.C. 67; Tenn. 360.
 - bale inquiry, 874.
 - blue stain, 197.

Cotton—Continued.

boll count, U.S.D.A. 115.
 boll, measurement of size, U.S.D.A. 115.
 bollweevil resistance, Okla. 66.
 breeding, La. 614; N.Mex. 181; Okla. 38; P.R.Col. 771; S.C. 39; Tenn. 325.

 root rot and weeds in native hay meadows, Tex. 797.
 root rot, control in irrigated Southwest, U.S.D.A. 58.
 root rot fungus, concentration of ammonia necessary to kill in low-lime phase of Houston clay soil, 205.
 rotation experiments, Fla. 38; La. 473.
 round-leaf, appearance and behavior of new strain, 767.
 rust, effect on quality, yield, and relation to potash, N.C. 641.
 sea-island, hybridization experiments, S.C. 39.
 sea-island, production, pure seed requirements, Ga. 777.
 seed treatment and irrigation tests, N.Mex. 181.
 seedbed preparation and planting, La. 181.
 seedling diseases, S.C. 54.
 soils, black, of Central Provinces, India, 162.
 spacing tests, Ala. 320; La. 181; S.C. 39.
 staple lengths produced in South Carolina, chart, S.C. 117.
 Texas, quality, U.S.D.A. 719.
 top dressing, tests, Ga.Coastal Plain 38.
 varieties for Missouri, Mo. 477.
 varieties grown by Tennessee farmers, regional comparisons, Tenn. 477.
 varieties in adjacent rows, competition, 619.
 varieties, variation in fiber length, fineness, and maturity, S.C. 39.
 variety tests, Ga.Coastal Plain 38; La. 181, 473, 614; N.C. 327; N.Mex. 181; Okla. 38; S.C. 39; Tenn. 325.
 web-spinner in Queensland, 821.
 wilt, effect of potash fertilizers, Miss. 499.

Cotton—Continued.

- wilt in Mississippi Delta, potash for, 642.
- wilt, studies, S.C. 54.
- winter cover crops for, Ga.Coastal Plain 38; La. 181.

Cottonseed—

- cake, hardness, factors affecting, Tex. 82.
- hulls as roughages in fattening steers, Fla. 78.
- hulls, kafir silage, prairie hay, and alfalfa hay, comparison for calves, Okla. 78.
- invasion by *Bacterium malvacearum*, 58.
- linted and acid-delinted, comparison, 196.
- meal and hulls, feeding to fattening steers, S.C. 79.
- meal as feed for ponies, 672.
- meal, effect on dairy products, Okla. 90.
- meal feeding, effect on butterfat constants of goat milk, 95.
- meal, feeding value, Tenn. 375.
- meal injury, an incorrect term, Okla. 90.
- meal, making safe and effective for pigs, 672; Ohio 674.
- meal, physiological effect on dairy cows, N.Mex. 236.
- meal supplements for laboratory animals, Okla. 79.
- meal v. distillers' dried grain for fattening steers, Ky. 827.
- meal v. soybean oil meal in fattening ration, Ill. 374.
- oil, hydrogenated, factor essential for lactation in, Ill. 419.
- oil, ingestion before and after hydrogenation, effect on composition of body fat, 522.
- yields from use of fertilizers, S.C. 30.

- Cottonwoods, chlorosis, Wyo. 55.
- Cottony-cushion scale, P.R.Col. 814.
- Coumarin in *Melilotus dentata*, 623.
- Country, see Rural.
- County planning and zoning, enabling acts and commissions, U.S.D.A. 124.

Cover crops—

- as source of organic matter for truck gardens, Ill. 334.
- for vegetable culture, Fla. 43.
- use, Fla. 38.
- winter, comparison, Tenn. 325.
- winter, for cotton and corn, La. 181.

Cow diseases, relation to disease in man, 244.

Cow manure, conserving nitrogen in, effect of superphosphates, Vt. 754.

Cowpea—

- aphid, studies, S.C. 67.
- group of nodule bacteria, new types, 171.
- hay and peanut hay as feed for sheep, comparison, 884.
- root knot-resistant strains, development, Fla. 53.
- weevil control, practical use of sun in, 226.

Cowpeas—

- and sorghum in rotations for summer cover and green manure, Fla. 38.
- culture under dry land conditions, N.Mex. 475.

- production tests, La. 614.
- seeding in corn, Tenn. 325.
- variety tests, Fla. 37; Ga.Coastal Plain 38; La. 181; N.Mex. 181; Okla. 38.

Cows—see also Calves, Cattle, and Heifers.

- wintering, leguminous roughage v. non-leguminous roughage with protein concentrate for, Ind. 374.
- with spring calves v. those with fall calves, cost of wintering, Ind. 374.

Cowsheds, condition, 711.

'Crab apples, flowering, production of hybrids and culture, 789.

'Crab meat of blue and sand crab, composition and nutritive value, Mass. 880.

'Crabs, Siberian, as rootstocks, tests, S.Dak. 44.

Crambus caliginosellus, see Corn root web-worm.

Cranberries—

- cold storage, Mass. 782.
- fertilizers and harvesting, N.J. 480.
- spraying and dusting, Mass. 782.

Cranberry—

- bogs, low-lift pumps for, Mass. 860.
- bogs, sanding, N.J. 488.
- bogs, weed control in, Mass. 771; Wash. 333.
- false blossom, control, N.J. 493.
- false blossom-resistant strains, development, Mass. 782.

Cranberry—Continued.

- flea beetle, notes, Mass. 815.
- fruitworm, N.J. 506.
- fruitworm parasite, Mass. 815.
- juice and cordial, preparation, Mass. 879.
- red leaf spot, cuprocide for control, Wash. 344.
- root grub, notes, Mass. 815.
- spittle insect, Mass. 815.
- storage, Mass. 800.
- vines, growth, effect of copper, Mass. 782.
- weevil, notes, Mass. 815.

Crane flies, new species from Puerto Rico, P.R.Col. 222.

Cream—

- and butter, sediment tests, comparison, Iowa 236.
- Babcock fat test and Mann acidity test, procedure, Calif. 692.
- bottled coffee, formation of milk layer in, 536.
- canned, discoloration and corrosion, 95
- cultured, body of, [N.Y.]Cornell 387.
- denaturing, use of annatto, Md. 692.
- farm-skimmed, enzymes in, Ind. 383.
- high quality, methods of production, Ill. 383.
- market, viscosity, 689.
- mold in, methods for estimation, 745.
- neutralization and churn losses of fat, 844.
- oxidized flavor, homogenization as preventive, 841.
- oxidized flavor in, effect of fat content, 841.
- properties, effect of homogenization at different temperatures, 692.
- quality, relation to amino nitrogen in, S.Dak. 91.
- retail, physical defects, 92.
- sediment in, test for, Okla. 90.
- sediment test, difficulties of application, Ind. 383.
- sweet, thick or thin, factors affecting, N.Y.State 843.
- testers, manual for, Md. 242.
- testing for butterfat, Ky. 95.
- transportation to New York market, [N.Y.]Cornell 122.
- whipped, composition and quality, effect of feeding untreated and disemittered vetch seed, 840.
- whipping, properties and quality of finished product, Mass. 383.

Cream puffs and eclairs, *Staphylococcus aureus* in, destruction, 419.

Creameries—

- distribution and costs of power and labor, Idaho 111.
- farmers' cooperative, organization and membership, Iowa 260.

Creamery and tester's licenses, Ind. 387.

Creatinine, new color reaction for, 10.

Credit unions—

- development, status, and types, 416.
- in Oklahoma, Okla. 260.

Cremona cotoneaster, life history, 73.

Crepidodera helvinae, notes, Conn.[New Haven] 813.

Cresols, relative toxicity, 510.

Cricket—

- field, as strawberry pest, 71.
- Mormon, increase in populations, Idaho 813.
- Mormon, invasion of Utah by bands of, Utah 67.

Cronartium ribicola, see White pine blister rust.

Crop gland—

- of hypophysectomized pigeon, effect of lactogenic hormone injections, 322.
- relation to growth, 681.

Crop—

- enterprises, southern, treatise, 878.
- insurance, selections and excerpts, U.S.D.A. 118.
- meter, U.S.D.A. 115.
- regions in Montana, relation to environmental factors, Mont. 774.
- reports, U.S.D.A. 124, 267, 558, 719.
- residues, manurial value, Ind. 325.
- rotations, see Rotation of crops.

Cropping systems—

- for maintenance of organic matter and nitrogen in soils, Okla. 13.
- leaching studies in relation to, Ill. 302.

Crops—see also Field crops, Forage crops, Root crops, and specific kinds.

- catch and special, for Nebraska, 614.
- composition, Iowa 158.
- composition of tissues and corresponding soils, spectrographic studies, Fla. 53.
- costs and practices with, Ind. 410.
- cultural methods, U.S.D.A. 182.
- effect on each other, Mont. 326.
- effect on succeeding crops, R.I. 771.
- growth, effect of electric current, Iowa 472.
- growth on soil types, effect of fertilizers, Iowa 158.
- new, for old lands, N.Y.State 286.
- production control, economics of, 711.
- production, role of less common elements, 106.
- production studies, Ill. 324; U.S.D.A. 182.
- quantities of fertilizers for, N.C. 300.
- response to fertilizer additions and fertilizer deficiency, Ind. 302.
- shrinkage in storage, Ill. 324.
- soil-depleting and soil-conserving, acreages, Iowa 200.
- studies at United States Dry Land Field Station, Ardmore, S.Dak., U.S.D.A. 286.
- suitable fertilizer mixtures for, N.C. 25.
- table showing productivity balance, manure equivalent, percentages of rotated areas, Ohio 711.
- yields and net costs per bushel and net profit per acre, Ill. 410.

Crops—Continued.

- yields, and nutrients in lower main stems, relations, analyses, 615.
- yields, effect of shelterbelt, Wyo. 40.
- yields, effect of sod crops, U.S.D.A. 182.
- yields, effect of tillage, Wyo. 40.
- yields from tile drainage, no drainage, and surface drainage, Ohio 615.
- Crotalaria*—
 - culture experiments, Ga.Coastal Plain 38.
 - feeding value, Fla. 90.
 - manurial efficiency, photoperiodism as factor, 620.
 - poisonous to livestock in Florida, Fla. 99.
 - rotation experiments, Fla. 38.
 - variety tests, Ga.Coastal Plain 38; La. 181, 614; S.C. 39.
- Orotalaria*—
 - intermedia*, rate of planting and stage of cutting tests, Fla. 38.
 - retusa* seeds, toxicity for chickens, 356.
 - spectabilis* seed poisoning in poultry, pathology, 401.
- Crown gall—
 - bacteria, nitrogen metabolism, 494.
 - development, growth hormone in, 197.
 - tissues, effect of enzymes and amino acids, 201.
- Crows, relation to waterfowl on their breeding grounds, U.S.D.A. 800.
- Crucifer club root, control, 197.
- Cryolite—
 - as insecticide for tobacco, Tenn. 360.
 - as substitute for lead and arsenic, Tenn. 360.
 - for checking apple flea weevil damage, Ill. 359.
 - orchard experiments for codling moth control, 819.
- Crypteropsis orbus*, notes, 821.
- Cryptocephalus incertus* on cranberry, Mass. 815.
- Cryptococcus fagi*, see Beech scale.
- Cryptognatha nodiceps*, parasite of coconut scale, 823.
- Cryptolaemus*, adaptability to mealybug control, Mass. 814.
- Cryptorchid swine testicles, hormone production in, 323.
- Cryptorchidism—
 - experimental, in Wistar rat, 472.
 - in sheep, inheritance, 317.
- Cube root and derris, toxicity, comparison, 70.
- Cube root extracts, optical rotatory power, 70.
- Cucumber—
 - beetle, striped, control, Conn.[New Haven] 813; Wis. 506.
 - beetle, striped, notes, Me. 66.
 - beetles, studies, Ind. 360.
 - fruit rot, notes, P.R.Col. 795.
 - mildew control, P.R.Col. 795.
 - mosaic in Puerto Rico, 196.
 - nematodes, notes, N.J. 493.

Cucumber—Continued.

- powdery mildew in greenhouse, spraying for, Mass. 794.
- Cucumbers—
 - cost of production, U.S.D.A. 261.
 - growth, effect of alternate periods of light and darkness of short duration, 27.
 - preservation by salting and fermentation, Mass. 879.
- Cucurbit diseases, Del. 190; S.C. 54.
- Cucurbit downy mildew, notes, Fla. 53.
- Cucurbits, inherited shape differences in, analysis, 34.
- Culture medium, brilliant green bile, growth-promoting and growth-inhibiting substances in, 93.
- Cuprous oxides, makes, as seed treatment for damping-off control, 344.
- Curly top on vegetables and other susceptible hosts in the Pacific Northwest, U.S.D.A. 53.
- Currant—
 - bud mite, control, 219.
 - fruitfly, biological studies and control, Oreg. 223.
- Currants—
 - photosynthesis in, effect of environal factors, 761.
 - Red Lake, new variety, N.Y.State 193.
 - Viking, immunity from white pine blister rust, 650.
- Ouscuta*—
 - glomerata*, host plants, 638.
 - invasion, gall formation in host plants following, 795.
- Cutworm—
 - bait, improved, from lubricating oil, Ill. 359.
 - bait, value of early application, Wis. 506.
 - dark-sided, notes, Conn.[New Haven] 362.
 - pale western, control, Mont. 66.
 - pale western, control, importance of, Utah 67.
 - variegated, notes, Tenn. 360.
- Cutworms—
 - on soybeans, control, Ill. 359.
 - studies, Ind. 360.
- Cyclohexylamine derivatives, contact, insecticidal properties, 68.
- Cylas formicarius*, see Sweetpotato weevil.
- Cylindrocarpum obtusisporum*, notes, 354.
- Cystine gelatin as medium for differentiation of *Salmonella pullorum* from *S. gallinarum*, 402.
- Cysticercus bovis*, immunizing cattle against, 696.
- Cystine—
 - amine, failure to substitute for cystine in animal nutrition, Ill. 374.
 - in gluten from toxic wheat, 442.
- Cytology, recent advances in, treatise, 765.
- Cytospora kunzei* canker of spruce, 651; U.S.D.A. 53.

- Dactylosternum abdominale*, notes, Hawaii 99.
- Daguis* new genus, description, 666.
- Dahlia bacterial soft rot, Utah 54.
- Dahlia, testing, N.J. 480.

at Tucumcari Field Station, N.Mex. 474.
in northcentral Montreal, Mont. 825.
- Duck disease with symptoms of vitamin deficiency and infections, 703.

Duck hybrids, sex-linked characters in, 467.
Ducklings, scientific fattening, 681.

Ducks—

- avian tuberculin tests of, 255.
- geese, pheasants, and turkeys, comparative growth rates, 686.
- intergeneric hybrids, 466.
- Khaki-Campbell, studies, 680.
- mallard, semidomesticated, ecology, Iowa 215.
- native wild, ecology, Iowa 215.
- nematode parasite of, 214.
- young, optimum protein levels in rations, Ind. 375.

Duff hygrometer calibration, technic, 791.

Duty of water, *see* Irrigation.

Dyes and methods affecting methylene blue test, Vt. 848.

Dysentery of young animals, treatment with acidophilus milk, 106.

Ear vesicles, abortive differentiation in waiting mice, 318.

Earth, rammed—

- and sun-dried, for construction of farm buildings, 865.
- for farm building walls, S.Dak. 109.
- walls in poultry house construction, S.Dak. 109.

Earthworms in greenhouses, destruction by hydrated lime, Ill. 360.

Eating utensils, bacteriological examination for sanitary quality, 725.

Echinococcus granulosus, larval stage, experimental immunization of sheep against, 701.

Echinostoma spp., notes, 656.

Ecology, adaptation and origin, 166.

Economic system, requirement for business, 92.

Economics, agricultural, *see* Agricultural economics.

Education—

- of farm owners and tenants in Tennessee, Tenn. 721.
- of heads of households and children in Texas relief population, 560.
- vocational, in the States, policies for administration, 878.

Eelgrass wasting disease and environmental conditions, 796.

Eelworm, black currant, control, 219.

Egg—

- albumin, *see* Albumin, egg.
- consumption, need for, 682.
- production—*see also* Hens, laying.
 - and hatchability, effect of calcium and phosphorus in rations, 530.
 - and prices, seasonal variation in, 712.
 - and viability, breeding for desirable factors in, Del. 227.
 - biological value of meat scrap and milk, Iowa 228.
 - breeding for, Mass. 827.
 - changing trends in, N.J. 527.
 - costs, profits, size, etc., effect of artificial lights, Del. 260.

Egg—Continued.

production—continued.

- effect of removal of comb from pullets, [Conn.] Storrs 466.
- feeding for, Fla. 78.
- fertility, and hatchability, relation between, 381.
- for local consumption in Middle Rio Grande Conservancy District, N.Mex. 715.
- in England, economics of, 682.
- inheritance in fowls, 610.
- lights v. no lights for White Leghorn pullets and hens, Fla. 78.
- low protein v. high protein for, Okla. 78.
- protein sources, Fla. 78.
- winter, relation of pauses in, to number and size, Wyo. 80.
- propagation of fowl pox and infectious laryngotracheitis, 253.
- yield records, winter and summer fall, usefulness, N.J. 86.
- yields, quantity and quality, measurements, N.J. 87.
- yolk, carotenoid pigments in, relation to those in feed, 528.
- yolk color, feeding for, Okla. 79.
- yolk, correlations between fresh and storage measurements, 682.
- yolk, experimental changes of pigments in in reference to vitamins, 680.
- yolk, vitamin A content, 233.
- yolks, fresh and storage, cholesterol in, Ky. 827.

Egg-laying contests, mortality in, N.J. 527.

Eggplant—

- bacterial wilt, control, P.R.Col. 795.
- fruit rot and wilt, notes, N.J. 493.
- fruit rot associated with *Pythium*, P.R.Col. 795.
- Verticillium* wilt, Mass. 794.
- Verticillium* wilt, effect of bordeaux and copper sulfate dust, Ill. 343.

Eggplants—

- breeding for disease resistance, P.R.Col. 795.
- cost of production, U.S.D.A. 261.
- fertilizer requirements, P.R.Col. 783.
- frost protection for, Fla. 12.
- pavement ant injury to, 373.
- production, U.S.D.A. 783.

Eggs—

- aging, variations of pH and freezing point, 681.
- black rot in, cause, 382.
- buying for household, quality demands in, Vt. 893.
- chemical structure, changes during laying periods, 681.
- clean, production, Mo. 686.
- consumption in countries of world, 682.
- control in Germany, 682.
- diminishing fluctuations in production and sales, possibilities, 682.
- formation of chalazas in, 87.

Eggs—Continued.

- fresh and preserved, use of Wood's lamp for distinguishing, 682.
- freshness, control, 682.
- hatchability—
 - among Ohio hatcheries, 87.
 - and eggshell formation, effect of calcium intake levels, R.I. 837.
 - as related to seasons and hour of laying, 530.
 - determination, 682.
 - effect of environment and heredity, [Conn.] Storrs 837.
 - effect of vitamin A levels in ration, 233.
 - from normal and Creeper hens, and reciprocal crosses, [Conn.] Storrs 406.
 - relation to seasons and hour of laying, 523.
 - studies with certain feeds, 682.
- immature and laid, nitrogen content, 234.
- impregnated with iodine, production and uses in treatment of childrens' ailments, 681.
- in Belgium, production, trade, and consumption, 682.
- in Norway, production and regulated distribution, 682.
- incubation, *see* Incubation.
- interior quality—
 - factors affecting, Wash. 375.
 - relation to hatchability, 87.
 - value of minerals for, Ill. 374.
- iodine in, effect of kelp meal feed, 681.
- loss in quality through packing methods, 680.
- loss of weight during incubation, 235.
- market, composition, relation to external qualities, 682.
- marketing under U. S. grades and on graded basis, Ind. 375.
- Norwegian, classification, condition of yolk and air cell as criterion, 682.
- not fertilized in ovary, 323.
- percent firsts as measurement of egg size in pullet yields, N.J. 234.
- percentage marketed by different methods, R.I. 867.
- physical and physiological characters in, 681.
- physical quality, S.C. 79.
- preservation, evaporation cooler for, Okla. 78.
- prices, recent rise in, causes, 712.
- principal markets, effect of changes in international price levels, 262.
- quality, characters of breeds, variations in, 685.
- quality, factors affecting, Pa. 79.
- quality, production, and mortality, effect of rations, N.Mex. 228.
- quality studies, 681.
- shape of, 681.
- shell, temperature changes in, factors affecting, 680.

Eggs—Continued.

- storage, progress in research on, 879.
- viscosity, measurement by use of torsion pendulum, 685.
- vitamin A and D in, effect of diet, Iowa 228.
- weight and weight of chicks at hatching, correlation, N.J. 527.
- yield, effect of condensed buttermilk, Ind. 375.
- yolk index, percentage of firm white, and albumen index, relations, 529.
- Eggshell—
 - color in given strain, variations in, N.J. 527.
 - membranes, pigment from, 685.
- Bimeria myatrii* infection, relation to diet, 696.
- Elmian infections in pigeons, oocyst production, 558.
- Blasophora poelli* in African buffalo and taxonomic affinities, 244.
- Electric—
 - currents, effect on crop growth, Iowa 472.
 - fence as control for livestock, Okla. 115.
 - fences, Ind. 403; Wis. 549.
 - iron, selection and use, Va. 575.
 - motors for farm machinery, 258.
 - range and cooking utensils, selection and use, 735.
- Electrical—
 - appliances, inspected household, list, 286.
 - power, distribution and costs in Idaho creameries, Idaho 111.
- Electricity—
 - and fuel as source of power, comparison, 258.
 - for English farmers, benefits and use, 258.
 - for operating equipment for fruit farm, 409.
 - heating hotbeds with, Ind. 403.
 - in agriculture, use, Ill. 403.
 - use, Me. 116.
 - use for soil sterilization and heating for tomato improvement, Ohio 706.
- Electrodialysis of soils by rotating electrode, 449.
- Electrokinetics, studies, Minn. 580.
- Elements, minor, relation to science of plant nutrition, 599.
- Elevators, cooperative, factors in success of, Okla. 116.
- Elk, Yellowstone, parasites, diseases, etc., 102.
- Elm—
 - bark beetle—
 - native, larvae, studies, 75.
 - native, tunneling habits, 359.
 - native, vector of Dutch elm disease, Mass. 814.
 - smaller European, dissemination by air currents, 507.
 - smaller European, notes, Del. 215.
 - Cephalosporium* wilt, 210.
 - Chinese, Texas root rot of, N.Mex. 200.

Elm—Continued.

- dic-back, *Dactioidella* n.sp. causing, 807.
 disease, Dutch—
 eradication, U.S.D.A. 342, 794.
 in Europe, 196.
 insect vectors, Mass. 814.
 possible mite vectors, 521.
 spread, relation to wind drift, 648.
 status, Conn.[New Haven] 637;
 Ohio 637.
 diseases in Massachusetts, Mass. 795.
 diseases in nurseries, tests of fungicides
 for, 807.
 infection by *Ceratostomella ulmi*, rela-
 tion to injuries, 198.
 insects in Connecticut, hymenopterous
 parasites, Conn.[New Haven] 813.
 leaf beetle, notes, 659; Conn.[New
 Haven] 813.
 root disease, due to *Verticillium*, 210,
 648.
 root rot disease, Ohio 637.
 scale, European, increased abundance,
 Ill. 360.
 seed, American, storage and dewinging,
 791.
 wilt-inducing fungi, distribution by sap
 stream, 196.

Elms—

- photosynthesis in, effect of environal
 factors, 761.
Thyrostoma compactum on cankerous
 tissues, 63.
Elaeagnus australis, studies, 208.
 Embankments, construction, underground
 sliding caused by, stability measures, 404.
 Emmer, digestible nutrients and metaboliza-
 ble energy, 673.
Empoasca fabae, see Potato leafhopper.

Encephalitis—

- equine, epidemic, in Japan, 849.
 equine, midwinter, in Indiana, 545.
 notes, Ind. 391.

Encephalomalacia—

- and vitamin B₁ deficiency in chicks, dif-
 ferentiation, 838.
 field, of chicks, 89.

Encephalomyelitis—

- equine—
 epidemiology and control, 107.
 in Panama, 252.
 in western Montana, 245.
 outbreak, losses of undetermined
 cause following, 702.
 studies, 848; Md. 695.
 transmission by *Aedes taeniorhyn-*
 chus, 702.
 virus strains and lymphocytic chori-
 meningitis virus, differentiation,
 545.
 virus, transmission to vulture, 401.
 of sheep associated with *Listeria* infec-
 tion, 697.
 spontaneous, of mice, new virus disease,
 539.

Encyrtus infelix, biology and relations with
 host, 359.

Endamoeba histolytica, rats as reservoir for,
 246.

Endocrine glands, weights in Bantam fowls,
 36.

Endophyllum sempervivi, notes, 806.

Endothia parasitica, notes, Conn.[New
 Haven] 636.

Engine performance with gasoline and alco-
 hol, 257.

Engineering—

- comprehensive point of view, U.S.D.A.
 707.
 experiment stations, personnel and funds
 available, 255.
 upstream, human value in, U.S.D.A. 707.
Entedon tochyptrelli, parasite of apple cur-
 culio, N.Y.State 75.

Enteritis—

- hemorrhagic, in feeder cattle, *Salmonella*
 newport from, Ky. 848.
 in fowls, 703.
 of poultry in Turkey, 703.
 ulcerative, of turkeys, diagnosis, Mass.
 856.

Enterohepatitis, infectious—see also Black-
 head.

 summary, 401.

Enterotoxemia, causal organism and con-
 trol, 399.

Enterotoxemic jaundice of sheep and cattle,
 700.

Entomological—

- equipment and methods, manual, 810.
 history, fragments, treatise, 358.
 Entomology—see also Insects.
 economic, developments, 657.
 general, textbook, 213.
 introduction, treatise, 810.

Enzymes—

- action, mechanism, 149.
 in crown-gall and noninoculated plant
 tissue, comparison, 197.
 selective adsorption by cellulose, 5.

Ephestia—

- clutella*, see Tobacco moth.
 figulicella, see Raisin moth.
 kuehniella, see Flour moth, Mediter-
 ranean.

Ephialtes acqualis, notes, 366.

Ephydriidae, descriptions of genera and spe-
 cies, 606.

Epiblema strenuana and parasites, studies,
 73.

Epicauta—see also Blister beetles.

maculata, see Blister beetle, spotted.
 varivestis, see Bean beetle, Mexican.

Epitetranychus althaeae, notes, 671.

Eptiria—

cucumoris, see Potato flea beetle.
 parvula, see Tobacco flea beetle.

Epochra canadensis, see Currant fruitfly.

Equines—

- parasites in Panama Canal Zone, 244.
 relation of age of host to number of
 strongylid parasites, 855.

Erannis tilharia, see Lime-tree looper.

- Ergosterol, irradiated—
and vitamin D of cod-liver oil, identity, 889.
effect on *Trichinella spiralis* of rats, 245.
- Eriophyes—
carinatus, life history, 826.
ribis, see Currant bud mite.
- Eriosoma lanigerum*, see Apple aphid, woolly.
- Erosion, see Soil erosion.
- Erwinia—
amylovora blighted shoots, aerial bacterial strands on, 804.
amylovora, notes, N.J. 60.
amylovora, variability in, 345.
carotovora, notes, Fla. 54; Utah 54.
- Erysipelas outbreak in turkeys, 858.
- Erysipelothrix rhusiopathiae*—
culture medium for, 394.
in turkeys, 858.
notes, Mass. 856.
- Erysiphe—
graminis hordei, notes, 108.
polygoni, notes, U.S.D.A. 343.
polygoni on Delphinium, 62.
polygoni, tolerance to low humidity, 638
- Erythroneura—
comes, see Grape leafhopper.
comes zizao, control, Mont. 66.
- Escherichia coli—
electrophoretic mobility, effect of X-rays, Pa. 142.
electrophoretic potential, effect of electrolytes added to growth media, Pa. 142.
- Escherichia-Aerobacter—
from milk on Eijkman medium, reaction and productivity of media, 535.
group, acid production by, 602.
group, effect of brilliant green bile medium, 93.
group of organisms in milk, test media for, 386.
in milk, detection and significance, 690, 691.
organisms in brilliant green bile medium containing sodium formate, increased growth and gas production, 94.
- Eskimos in Canadian Eastern Arctic, metabolic studies, 565.
- Ethylene—
acceleration of ripening in bananas by, 461.
penetrability of orange and banana tissues to, 490.
- Etiella zinckenella*, see Bean pod borer, lima.
- Eucephalobus nannus* n.g. and n.sp., description, 808.
- Eucyathostomum longesubulatum*, parasite of Trinidad deer, 213.
- Eumicrosoma benefica*, egg parasite of hairy chinch bug, 359.
- Eupelmus limneriae*, notes, 821.
- Euplectrus agaristae*, parasite of grapevine moth, biology, 826.
- Euryhelms squamula* in United States, 245.
- Eurytoma—
fellis, morphology, biology, etc., 826.
tylodermatis, parasite of apple curculio, N.Y.State 75.
- Euschistus* spp., rearing method, 358.
- Eusmilium pecuarum*, studies, U.S.D.A. 215.
- Eutermes exitiosus* mound colonies, destruction, 816.

treatments and cropping, Wash. 302.

Fertilizers—

acid, value of dolomite and raw phosphate as neutralizers, 594.

acid-neutral, for vegetables, 595.

analyses, Mont. 25; N.J. 25.

effect on farm crops, Wis. 443.

effects in crop rotations, Iowa 157.

equivalent acidity and basicity, determination, Ind. 302.

evolution of market for, 204.

home mixtures, data, N.J. 25.

Fertilizers—Continued.

- inspection and analysis, Ind. 756; Mo. 454; N.H. 25; N.J. 454.
 nitrogenous, and soil acidity, Conn.[New Haven] 587.
 non-acid-forming, value of different basic materials and of dolomitic limestone, 594.
 studies, 25.
 use on representative upland soils, Wash. 302.
 Fescue, breeding, N.J. 473.
 Fiber, crude, *see* Cellulose.
 Field—
 crops—*see also* Crops, Forage crops, Root crops, etc.
 for planting in South Dakota, S.Dak. 784.
 experiments, efficiency of incomplete and randomized block methods, 771.
 experiments, importance of replication and randomization in design, 771.
 Filbert blight, control, 807.
 Filberts, breeding and description of hybrids, 177.
 Fir, Douglas—
 bacterial gall disease, vector of, Calif. 648.
 die-back, 63.
 growth of trees of known seed source, U.S.D.A. 51.
 Fir engraver, life history, habits, and distribution, U.S.D.A. 224.
 Fir trees, annual ring widths, 341.
 Fire beetle on cranberry, Mass. 815.
 Fire blight—
 aerial bacterial strands, 197.
 and apple scab, combined control, 197.
 organism, variability in, 345.
 Fire control notes, U.S.D.A. 492.
 Firebrat and gregarine parasites, 360.
 Firebrick, crushed, as rooting medium for greenhouse and nursery plants, Iowa 190.
 Fires—
 farm, and effectiveness of spark arresters, Iowa 255.
 forest, *see* Forest fire(s).
 Fireworm—
 black-headed, on cranberry, Mass. 815.
 control, Wash. 301.
 Fish—
 byproducts for poultry, Wash. 375.
 home canning, 563.
 meal, biological value, 232.
 meal for fattening hogs, Nebr. 674.
 meal for growth and milk production, Ohio 533.
 meal, meat scrap, and milk solids, comparison for egg production, Fla. 78.
 meal-sea kelp preparation, effect on reproduction in cows, N.J. 532.
 meals, preparation and biological value, 228.
 oils, vitamin D of, multiple nature, 676.
 Fishes—
 reaction to sex hormones, 770.
 relation of birds to, U.S.D.A. 652.
 selenium poisoning in, 538.

- Flannel properties, effect of kind of wool, S.Dak. 140.
 Flat-headed borer, life cycle, Okla. 66.
 Flatworms in poultry, control and prevention, Ill. 546.
 Flavine—
 extraction and stability, 570.
 in cereals, 136.
 in cheese, 429.
 response of rats, chicks, and poultis to, 81.
 Flavone fraction of lemon juice, crystalline, nature, 740.
 Flavones, vitamin nature, 739, 740.
 Flax—
 date of seeding experiments, Mont. 326.
 diseases and pests, 55.
 diseases in Iowa, Iowa 200.
 new to Illinois, Ill. 324.
 production tests, La. 614.
 seed and fiber, production tests Fla. 38.
 seed-borne plant pathogens, treatment for, Iowa 200.
 seed, variety tests, N.J. 473.
 seedlings, fungi injurious to, 348.
 tillage experiments, U.S.D.A. 774.
 variety tests, Ill. 324.
 yields, effect of tillage, Mont. 325.
 Flaxseed—
 effect of organic mercury dusts, Iowa 200.
 germination, factors affecting, 779.
 oil content and quality, rapid determination, U.S.D.A. 7.
 Flea beetles, injurious to citrus in China, 372.
 Fleas, control, crude naphthalene for, Ill. 300.
 Fleece sampling and analysis, methods, 677.
 Flesh fly, control, 348.
 Flickers, natural hybridization and genetics, 768.
 Flies—
 house, *see* Housefly.
 white, *see* Whiteflies(y).
 Flood—
 control, conservation farming practices, U.S.D.A. 19.
 discharges and rainfall, graphic presentation, 110.
 Florida—
 Station, notes, 895.
 Station, report, 141.
 University, notes, 287, 895.
 Florigen, use of term, 758.
 Flour—*see also* Bread.
 baking strength, 440.
 beetle, confused—
 insect fumigants for, relative toxicity, Minn. 660.
 prothetely in larvae, 225.
 reduction in fecundity due to eating its own eggs, 823.
 relative effect of paris green homologs, 813.
 diastasis in, identification and measurement of factors, 297.

Flour—Continued.

- diastatic activity, determination, refractometric methods, 440.
- enzymes of, Nebr. 580.
- finishes for household use, R.I. 892.
- from Fulhio wheat and cooking qualities, Ill. 418.
- grade and baking characteristics, Nebr. 580.
- milling, atmospheric factors in, 441.
- moth, Mediterranean, resistance to high temperatures, 368.
- strength, definition and measurement, 439.
- sulfur dioxide in, detection, 441.
- viscosity, report of subcommittee, 438.

Flowers—see also Plants, flowering, and Plants, ornamental.

- for planting in South Dakota, S.Dak. 784.

Fluids—

- biological, total base in, determination by electrodialysis, 9.
- consumption by 1,000 residents of New York, 884.

Fluke—

- new, from American bittern, 655.
- small, in turkey poult, deaths from, 706.

Fluorine—

- and mottled teeth in Maldon, Essex, 728.
- in diet, value of aluminum salts for combating, Wis. 562.
- intake, low levels, effect on bones and teeth, 276.
- of water in Foochow and dental defects, 728.

Fly sprayers, use, Wis. 506.

Foaming, prevention in crude-fiber determinations, 8.

Fodder crops, see Forage crops.

Folliculosterone, chemical nature and synthesis, 613.

Fomes—

- fomentarius*, spore formation and discharge in, 795.
- ignarius*, variation in, Minn. 651.

Food—see also Diet.

- allergy and dietitian, 273.
- and nutrition studies, Iowa 272.
- and principles of dietetics, treatise, 561.
- buying for household, quality demands in, Vt. 892.
- calcium and phosphorus in, relation to calcium in body, 727.
- consumption of Wisconsin relief families, Wis. 564.
- control, significance of poultry diseases in, 703.
- costs, consumer's, farmer's share from, U.S.D.A. 123.
- elements, utilization by growing chicks, Nebr. 838.
- habits and nutritive instincts of superior individuals as guides to nutritional requirements of group, 673.

Food—Continued.

- imports and Italian sanctions, 712.
- ingestion, changes in skin temperature following, 274.
- poisoning in England due to *Salmonella aertrycke* infection in man, 851.
- poisoning, staphylococcus, and production of an enterotoxin substance in bread and meat, 277.
- production for local consumption in Middle Rio Grande Conservancy District, N.Mex. 715.
- supplies and consumption at different income levels, 711.
- supplies, home production, Tenn. 415.
- utilization, breeding for efficiency, 466.
- vitamin B₄ distribution in, Wis. 562.

Foods—

- acid and alkali forming, 275.
- African, composition, 375.
- and drugs, examination, Me. 725.
- ascorbic acid in combined state in, 426.
- canned, see Canned foods.
- gums in, detection, 745.
- iodine in, Mass. 739.
- preparation and storage, recent developments in, 879.
- zinc determination in, 206.

Foot-and-mouth disease virus, purified, properties, 246.

Forage—

- A. I. V., conservation, 229.
- A. I. V., for dairy cow, effect on quality of milk, 533.
- and pasture crops, symposium, 776.
- crops, artificial curing, Pa. 109.
- crops, artificially dried, feeding value, Wash. 383.
- crops, Florida, ensilability, Fla. 90.
- crops for fattening hogs, comparison, S.C. 79.
- crops, variety tests, Ga. Coastal Plain 38; N.Mex. 181; Wyo. 40.
- grasses, see Grasses.
- green, water in, technic for determining, Iowa 180.
- increased use in livestock production, 672.
- poisoning, see Livestock poisoning.
- Plants, poisonous, and specific plants.
- range, calcium and phosphorus in, N.Mex. 522.

Forages, grazing, phosphorus and calcium content, N.Mex. 228.

Forest—

- economics, research in, survey, 869.
- fire control, Ohio 634; U.S.D.A. 196, 791.
- fire insurance in Pacific Coast States, U.S.D.A. 52.
- fires in longleaf pine region, soil fauna associated with, 210.
- insects, biological control, 815.
- insects of Great Britain, 815.
- insects, survey, Ohio 658.
- lands, management and use, U.S.D.A. 707.

Forest—Continued.

- lands, soil erosion and stream flow on, relation to land resources and human welfare, U.S.D.A. 863.
- mensuration, elements, 196.
- News of Ohio, Ohio 50, 492.
- nurseries, disease developments in, 197.
- nursery stock, propagation and distribution, Conn.[New Haven] 634.
- nursery stock, success in, relation to soil conditions, Wis. 447.
- plantations, fungi and diseases in, development and succession, 356.
- plantings, experimental, competition in, Pa. 50.
- products from maple sugar orchards, Vt. 870.
- resources and major forest problems of Oregon, 193.
- soil fertility, pot culture tests, 634.
- soils, two contrasting, studies, 50.
- trees, *see* Trees.
- types, distribution in Arkansas, soil characters affecting, 51.

Forestry—

- and permanent prosperity, U.S.D.A. 50.
- statistics, international yearbook, 416.

Forests—

- and parks, State, development, Ohio 634.
- Mediterranean, effect on climate, 156.
- national, erosion control engineering, handbook, U.S.D.A. 309.
- of South Dakota, importance and possibilities, U.S.D.A. 491.
- State, improvement cuttings and replantings in, Ohio 634.
- State, management, Conn.[New Haven] 634.

Formaldehyde—

- dust prepared with different absorbents, stability, Ohio 495.
- protective agent for wool, Iowa 283.

Formamide as nitrogenous fertilizer, 24.

Fossaria olivæ, intermediate host of *Fasciola gigantica*, 521.

Foundin, treatment of undulant fever with, 105.

Foulbrood—

- American, notes, 825.
- American, resistance to in bees, 373, 520.
- American, variation in resistance by bees, Iowa 215.
- European, studies, 76.

Foundation—

- analysis, Jürgenson's method, Gilboy's presentation, 404.
- loads, distribution of stress in underground due to, 404.
- soils, testing, and soil consolidation, theory, U.S.D.A. 257.

4-H club—

- program, effectiveness as regards farm attitudes, Ill. 417.
- work in life of rural youth, 271.

Fowl—

- cholera, N.J. 546.
 - cholera, new experiences, 703.
 - cholera, summary, 108.
 - coryza, *Hemophilus gallinarum* in spleen, 546.
 - paralysis, *see* Paralysis.
 - pest virus, attenuation by X-ray, 253.
 - pox and Kukuth's canary disease viruses, immunological relation, 253.
 - pox and leukemia, pathogenic effect, differential diagnosis, and control, 704.
 - pox control, pigeon pox vaccine for, Ill. 390.
 - pox vaccination of day-old and older chicks, 108.
 - tapeworm, transmission, role of housefly in, 245.
 - typhoid, *see* Typhoid, avian.
- Fowls—see also* Chickens, Hens, Poultry, *etc.* and turkeys, protein requirements, comparison, Idaho 826.
- Bantam, endocrine gland weights, 36.
 - Barred Rock, bilateral gynandromorphism in, 466.
 - blood group antigens in, inheritance, 611.
 - body size, differences in, basis for, 178.
 - chromosomes in, morphology, 464.
 - closely confined, fecundity and reproductive ability in, 683.
 - composition of body fat, effect of different cereals in fattening rations, 683.
 - creeper, heterogeny in axial skeleton, 36.
 - creeper, lethal mechanism of creeper gene, 178.
 - distant hybridization by artificial insemination, 467.
 - external parasites, effect of sulfur, 858.
 - flightlessness, lethal nature, 469.
 - genetics, 610.
 - growth and hereditary size limitation in, Calif. 318.
 - growth and physical efficiency, hormone requisites for, 682.
 - growth rates, Iowa 228.
 - infected with intestinal parasites, oral exposure to *Salmonella aertrycke*, Fla. 254.
 - male genital ducts in, anatomy, 470.
 - moult in, physiology, 680.
 - native to different regions of Balkans, genes in, 318.
 - new lethal mutation involving abnormal maxillæ, 36.
 - origin of difference between size, 682.
 - peroxidases and formation of hemoglobin in development, 682.
 - rumpleness in, genetic modification, 319.
 - shank color in, inheritance, 610.
 - sperm tests with dilutors for, 467.
 - Styrian, breeding in Yugoslavia, 680.

Foxes—

red, food habits during drought summer in Iowa, 211.

silver and red, phenotypic variations in hair and colors, 610.

Fragrance in the garden, treatise, 341.

Frankliniella—

cephalica bispinosa, notes, Fla. 65.

vaccinii, notes, Me. 66.

Freon, effect on apples in cold storage, 192.

Frit fly resistance in oats, inheritance, 371.

Froghopper blight, control in West Indies, 513.

Frogs, parasites in North Carolina, 357.

Frost—

injury to bearing orange trees, 788.

problems in Florida, 12, 445.

protection service, Fla. 12.

resistance, relation to osmotic and bound water changes in plants, 311.

Fruit—

byproducts, utilization, Wash. 293.

circumeter, construction and use, 628.

disease situation in Illinois, U.S.D.A. 492.

diseases—

effect of water-table levels, 61.

in Idaho, U.S.D.A. 193, 493.

in Illinois, U.S.D.A. 493.

in Missouri, U.S.D.A. 492.

in New York, U.S.D.A. 493, 636.

in northern Virginia, U.S.D.A. 636.

in Rhode Island and in Virginia, U.S.D.A. 343.

on Chicago market, U.S.D.A. 203, 644.

studies, Idaho 794.

farm, electrification, 400.

farms, yields, costs, and net income, Ill. 410.

juice concentrates, preparation, N.Y. State 783.

juices, unfermented, preparation, N.Y. State 783.

moth, oriental—

bionomics and control, Del. 215.

breeding, 358.

control by parasites, 516; Ill. 359. in apple and peach orchards, Va. 820.

in Goulburn Valley, Australia, 222. parasites, Conn.[New Haven] 813; P.R. 826.

parasites, introduction in peach orchards, Mass. 814.

studies, 658; Conn.[New Haven] 657; Ind. 360; Ohio 658; Pa. 66; S.C. 67.

pests in Great Britain, 362.

pests in New Zealand, 815.

pollen, storage experiments, 784.

sprays, toxicity, 217.

tree leaf roller, control, Wis. 506.

tree little leaf or rosette, control, 803.

tree little leaf or rosette, relation to soil conditions, 61.

Fruit—Continued.

tree roots, growth and distribution, effect of drought, Nebr. 625.

trees, causes of failure to survive, Alaska 782.

trees, grafted to obtain own roots, 46.

trees, seedlings and budded, cost of production, Calif. 555.

trees, winter injury, types, Mich. 336.

washers, electric heaters for, Ind. 403.

Fruitfly—

Mediterranean—

infestations of oranges in Palestine, 666.

tests with Clensel bait, 371.

studies in west Africa, Hawaii.Sugar Planters' 519.

Fruits—see also Orchards, Apples, Peaches, etc.

breeding, Can. 625, 783.

bud mutations in, 176.

carlot shipments and unloads, U.S.D.A. 123.

Charleston as market for, W.Va. 121.

citrus, see Citrus.

cold storage, effect of humidity in, 192 consumption, importance of imports, 712.

crushed, use of dextrose in, Mass. 879. culture, 483.

cytology and breeding, 464.

dropping, relation to curculio sting injury, Del. 186.

frozen-pack, markets for, Tenn. 875.

grades, price trends, and sales on Indianapolis Producers' Market, Ind. 717.

grafting, pollination, pruning, etc., Can. 783.

growing in New York, relation to soils, [N.Y.]Cornell 308, 782.

hardy, for western Canada, 190.

hardy, growing, treatise, 483.

home bottling, 154.

interim report of Federal Trade Commission on, 874.

market diseases, U.S.D.A. 203.

marketing, [Conn.]Storrs 550.

marketing by motor truck in western Maryland, Md. 717.

marketing, changes in, N.J. 551.

metabolism, relation to preservation, 481.

Minnesota, market outlets for, Minn. 874.

new uses for, N.Y.State 180, 783.

new, variety tests, 46.

nutritional requirements, Can. 625.

old and new for planting in South Dakota, S.Dak. 784.

phenological studies, N.Mex. 186.

Philadelphia market for, Pa. 121.

pollination and setting, Mo. 190.

pollination, propagation, and utilization, Can. 625.

preservation by freezing, Oreg. 724.

Fruits—Continued.

- production for local consumption in Middle Rio Grande Conservancy District, N.Mex. 715.
 small, culture, 483.
 small, frozen pack, microbiological studies, 564.
 small, insect damage to, Utah 67.
 small, pest control problems, 360.
 small, studies, Alaska 782.
 small, varieties, Ill. 336; Okla 44
 sterilisation, use of bromine in, 203.
 stone, decreasing germination delay in, 192.
 storing, precooling, and freezing, Ind. 332.
 tropical and subtropical, vegetative propagation, 631.
 varieties, Can. 625.
 varieties in north Texas, Tex. 46.
 varieties, new, Md. 624.
 varieties, tree characters, Mass. 782.
 variety tests, Can. 783; N.Mex. 186; Wyo. 45.
 vitamins in, effect of processing, Mass. 568.
 winter injury in Idaho, U.S.D.A. 53.
 Fruitworm, notes, Wash. 361.
 Fuel and electricity as source of power, comparison, 258.
Fumex casta, prevalence, Conn.[New Haven] 813.
 Fumigation, vacuum, oxygen as factor, 507.
Fundella cistipennis, biological control, P.R. 826.
 Fungi—
 and diseases in forest plantations, development and succession, 356.
 attacked by larvae of gall midges, 821.
 freeing from bacterial contamination, method, 603.
 injurious to seedling flax, 348.
 parasitic on rusts, 639.
 phytopathogenic, physiological races, keys, Minn. 637.
 role in cotton damping-off or soreshin, 348.
 soil-infesting, causing diseases of ornamental plants, Mass. 795.
 temperature relations, 603.
 Fungicides—see also Sprays and specific analyses, Me. 186; N.J. 45.
 copper, see Copper.
 preparation to meet requirements of disease and host, 639.
 recent developments in, 793.
 tests on field tomatoes, Mass. 794.
 Fungus nomenclature, uniformity and stability, 793.
 Fur, Karakul, sheep breeding for production, 677.
 Furfural—
 production from xylose solutions, 438.
 properties and herbicidal action, Iowa 160.

Fusarium—

- aplii* n sp., type species, and form 2 a variety, Mich. 641.
bulbigenum lycopersici f. 1, provisional name, N.Y.State 207.
conglutinans, of vegetables new to Florida, U.S.D.A. 794.
culmorum, root rot diseases of cereals caused by, control, 202.
 diseases of rye, monograph, 797.
graminearum, toxic principle in wheat, barley, and corn, Minn. 250.
lateritium v. *fructigenum*, relation to wilt of China aster, 647.
lycopersici, notes, Fla. 54.
moniliforme, notes, 643.
niveum, notes, Fla. 54.
orthoceras, notes, 354.
poae on spring oats in Oregon, U.S.D.A. 198.
 sp., variation induced by high concentrations of zinc salts, 173.
 spp., cause of damping-off in mushrooms, 348.
 spp., distribution in nature, 792.
 spp., role in cotton damping-off or soreshin, 348.
rasmijectum, cotton wilt due to, 642.
 wilt of muskmelon, spreading in State, N.Y.State 801.
 wilt of White Burley tobacco, Ky. 794.
zonatum on onion in Iowa, Iowa 200.

Fusicladium—

- dendriticum*, see Apple scab.
saliciperdum in Vermont, U.S.D.A. 636.
 Future trading, statistical aspects on commodity exchange, 415.

Galactin—

- in rat pituitary, effect of suckling young, 179, 322.
 purification, 37.

Galerucella wanthomelaena, see Elm leaf beetle.

Gall—

- formation induced by *Cuscuta*, 795.
 midge attacking almond and peach buds in Greece, 821.
 midges, larvae attacking, 821.

Gallirua mellonella, see Wax moth.

Game—

- farm, increase in population, Wis. 506.
 of Alaska, regulations relating to, U.S.

Gardenia chlorosis, effect of soil temperature, Mass. 795.

Gardenias—

- bud-drop in, cause, N.J. 480.
 effect of nutrients, soil reaction, and light, Mass. 782.
 growth, effect of cloth tents, 49; Ohio 634.
 photoperiodic effects, Ohio 634.
 propagation, Mass. 782.
 Gardening, vegetable, treatise, 481.

- Gardens—
home vegetable, planting and care, Kans. 187.
wild, plant materials and culture, 490
- Garlic—
culture, Ohio 625; P.R.Col. 783.
wild, life history and control, Ill. 324.
- Gas—
analysis, new spectrographic method, 458.
in atmosphere and soil of greenhouse plants, effect, Mich. 758.
production from farm wastes, Ill. 403.
- Gasoline and alcohol blends for engine fuel, 257, 258; Idaho 860.
- Gassing power, manometric determination, 294.
- Gastric—
and duodenal ulcer, relation to sub-scurvy state, 138.
juice of dogs, ascorbic acid in, 887.
juice secretions of poultry under the influence of histamine, 681.
lesions in rats, relation to diet, 131.
- Gastrophilus*—
cqui larvae, physiology of digestion in, 855.
spp. of horses in New York State, 244.
- Geese, pheasants, turkeys, and ducks, comparative growth rates, 686.
- Gelatin—
and water solutions, effect of aging treatments on Tyndall phenomenon, Mass. 839.
supplemental value with hegarl proteins, 377.
- Gene concept and virus mutation, 317.
- Genes, symbols for, 604.
- Genetic terms, glossary, 464.
- Genetics research, relation to nutrition, 466.
- Georgia Coastal Plain Station, report, 142.
- Geranium* bacterial leaf spot, 647.
- Geraniums, propagation, Mass. 782.
- Ginseng, spreaders on, Ohio 637.
- Girls, basal metabolism, 130, 883.
- Gizzard—
erosions or lesions of chicks, cause, 676.
worm in wild waterfowl, 549.
worm, transmission to chickens in Hawaii, Hawaii 99.
- Gladiolus—
corms, basal dry rot, 197.
corms, effect of preheating on time of flowering, Ohio 634.
corms, shortening rest period, storage temperatures for, 490.
cytogenetic studies, Md. 624.
diseases in Iowa, control, Iowa 200.
scab control, N.J. 493.
thrips, control, spray materials for, Mass. 814.
thrips, destruction in storage, Ill. 359.
thrips, studies, Fla. 65; Ohio 658.
varieties, N.Mex. 186.
- Glanders bacillus and proteins from its culture, chemical analysis, 848.
- Glass cutter, inexpensive hot-wire, U.S.D.A. 216.
- Glassware, bacteriological examination for sanitary quality, 725.
- Giladin—
changes under action of flour and yeast proteinases, 439.
preparation, 147.
- Globulin, heat denaturation in milk, 384.
- Glomereilla gossypii*, role in cotton damping-off or soreshin, 348.
- Glossina*—
morsitans, control, 105.
spp., food hosts, 519.
- d*-Glucosascorbic acid, reversible enzymic oxidation of, 584.
- Glucose, fermentation by heterofermentative lactic acid bacteria, 585.
- Glutamine, metabolism in tobacco leaves, Conn.[New Haven] 580.
- Glutathione—
and ascorbic acid, relation, 152.
content of newborn rabbits, relation to adult weight, 179.
- Gluten from toxic wheat, partial hydrolysis products, selenium and cystine in, 442.
- Glutenin changes under action of flour and yeast proteinases, 439.
- Glycine in chick embryos and chondrodystrophy, 581.

 Infantile paralysis, see Poliomyelitis.
 Infants—see also Children.
 diet of, vitamin content, 421.
 feeding with individualized formulas, 726.
 irradiated yeast for, antirachitic value, 732.
 Influenza, human, virus—
 direct transmission to mice, 539.
 transmission to hedgehogs, 247.
 Inheritance, see Heredity.
 Inoculants, types, comparison, Ill. 324.
 Insect—
 forecasts, value of light and bait traps in, Ill. 360.
 fumigants, relative toxicity, Minn. 660.
 hemolymph, studies, 360.
 pest conditions forecast, 658.
 pests of field crops and animals, 815.
 therapy, scientific approach, 68.
 vectors of plant viruses, need of permanent reference collections, 508, 793.
 Insecticidal dusts, mixing, apparatus for, U.S.D.A. 216.
 Insecticides—see also Sprays and specific forms.
 action of, N.J. 506.
 analyses, Me. 186; N.J. 45.
 and therapeutic substances, effect on poultry, 703.
 chemical studies, Wash. 361.
 laboratory studies, methods and equipment, 68.
 organic compounds for, Del. 218.
 use in apple orchards, Conn. [New Haven] 657.
 worthless, importance of avoiding, Ill. 359.
 Insects—see also Entomology.
 affecting man, symposium, 68.
 and climate, studies, N.J. 506.
 and host, respiratory interrelation, new type, 358.
 and spiders, habits, 657.
 as pollinating agents in coffee groves, P.R.Col. 814.
 attraction to light traps, Nebr. 657.
 beneficial, for introduction into Puerto Rico, search in American tropics for, P.R. 508.
 beneficial, introduction and colonization in Puerto Rico, P.R. 508.
 biological control, 216, 670; Ill. 350.

Insects—Continued.

- biological control in British Solomon Islands, 815.
- biological control in New Zealand, 815
- biological control in West Indies, 508.
- common names approved by American Association of Economic Entomologists, 507.
- common names for, official, needed changes, 358.
- dissemination by air currents, 507.
- economic, studies, 815.
- forest, *see* Forest insects.
- freezing process in, Minn. 213.
- hibernating, method for examination in cocoons and webbing, U.S.D.A. 216.
- hibernation, role of water in, 657.
- injurious in Florida, Fla. 65.
- injurious to crops, *see* *special crops*.
- Nigerian, food plants of, 508.
- orchard and vegetable, spraying for, N.J. 506.
- orchard, control, 658.
- parasitic, extermination by use of poultry, 680.
- pollinating onions, 659.
- preparing whole mounts or parts for study, 657.
- role in transmission of virus diseases, 659; Me. 66.
- scale, *see* Scale insects.
- soil-infesting, N.J. 506.
- southern, moving northward during drought years, records, 508.
- subterranean, technic for rearing, 216.
- therapeutic uses, 68.

Insemination, artificial—

- experiment with airmail shipment of semen, 87.
- in dairy cattle, 93.
- in ewes, Idaho 826.
- in fowls, distant hybridization by, 467.
- in goats, 820.

Insulin, effect on urinary excretion of vitamin C in rats, 138.

Insurance—

- against livestock losses in France, 207.
 - cooperative and mutual, treatise, 416.
 - crop and livestock, in Bulgaria, U.S.D.A. 117.
 - crop, in dry areas of Alberta, 413.
 - forest fire, in Pacific Coast States, U.S.D.A. 52.
 - hail, 267.
 - life, carried by farmers in Alberta, 411.
- International Association of Dairy and Milk Inspectors, report, 847.

Iodine—

- absorption by food plants, Mass. 771.
- added, effect on properties and bacterial flora of milk, Mass. 839.
- blood, determinations, experiences in, 276.
- deficiency for New Zealand livestock, 377.
- effect on plant growth, Ky. 757.

Iodine—Continued.

- in bovine thyroid, Ohio 687.
- in crops and food materials, determination, 746.
- in eggs, effect of kelp meal feed, 681.
- in foodstuffs, new method for determining, Mass. 739.
- in milk, Ky. 842.
- in plant materials, soils, and fertilizers, Ky. 748.
- Iowa College, notes, 287, 736, 895.
- Iowa Station, notes, 287, 736, 895.
- Iowa Station, report, 286.
- Ipomoea, cytogenetic studies, Md. 624.
- Ips peribarbatus*, biology in Gaspé Peninsula, 225.
- Ips* spp., aseptic rearing, 812.
- Iridocyclitis outbreaks without paralysis in fowls, 401.

Iris—

- bacterial blight, 505.
- breeding, S.Dak. 44.
- bulbous, *Didymicella poecilospora* n.sp. on, 197.
- bulbous, nematode disease, control, 647.
- leaf disease, 197.
- testing, N.J. 480.
- varieties, Iowa 186.

Iritis, transmission by breeding hens, Utah 101.

Iron—

- absorption by food plants, Mass. 771.
 - and copper in metabolism, 133.
 - availability and distribution in plants, relation to pH of tissues, N.J. 455.
 - available in foods, Wis. 562.
 - compounds, reaction for determination of *Bacillus anthracis*, 302.
 - deficiency for New Zealand livestock, 377.
 - for blood regeneration, oral administration v. intraperitoneal injection in nutritional anemia, 728.
 - in home-grown foods, relation to anemia in children, Fla. 128.
 - in normal calf ration, Ohio 687.
 - in turnip and mustard greens grown on iron-deficient soils, Fla. 128.
 - in wheat, availability, 728.
 - reduction by tissue extracts and by ascorbic acid, 427.
 - reduction, intestinal, effect of vitamin D, 733.
 - requirement of pigs, Ill. 374.
 - role in crop production, 166.
 - storage, sex differences in, Wis. 562.
- Irradiation, *see* Ultraviolet.

Irrigation—

- conditions in Millard County, Utah, Utah 109.
- methods, Utah 110.
- practices in citrus orchards, records for checking, U.S.D.A. 489.
- project, Valier, analysis of agriculture on, Mont. 119.
- rotary spray, equipment for, Mich. 710.

Irrigation—Continued.

- sections, different sources of income, relative importance, N.Mex. 260.
- studies, Can. 783.
- supplemental, in humid region, 110.
- water carrying dissolved nitrogen fertilizer, nitrogen in, variation, Hawaii Sugar Planters' 754.
- water, duty of on citrus cultivation in Palestine, 489.
- water, duty trials in Sudan Gezira, 256
- water, effects of irrigation and cropping, N.Mex. 158.
- water, use on farm crops, 800.

Itame argillacea, notes, Me. 86.

Itch mite in foxes, prevention and control, 253.

Itihyocerus noveboracensis, see New York weevil.

Itoplectis conquisitor, notes, 366.

Iwodes—

- attack of lambs, bacterial infection as sequel, 544.
- ricinus californicus*, host and locality records, 397.
- ricinus californicus*, possible vector of *Bacterium tularense*, 397.

Japanese beetle—

- control, Conn.[New Haven] 657.
- destruction, relation to microbiological population of soil, N.J. 506.
- in Connecticut, Conn.[New Haven] 813.
- notes, Del. 215.
- populations, abundance, seasonal trends, 667.
- repellents for, 76.
- stomach poison and repellent for, 507.
- studies, Ind. 360.
- suppression in St. Louis, progress, 822

Jellies, fruit, role of pectin in, Del. 4.

Jerusalem-artichokes—

- irrigation test, Wyo. 40.
- new to Illinois, Ill. 324.
- variety tests, Nebr. 614.

John's disease—

- checking through repeated testing and sanitation, Ill. 390.
- recovery from, 244.
- vaccination against, 244.

Johnson grass, control, N.Mex. 182.

Juices, fermented, storing experimental lots, 443.

June beetle—

- green, trapping for, Ky. 814.
- larvae in tobacco beds, poison bran bait for, Ky. 814.

Juniper webworm, biology and control, 365

Kafir—

- grinding, value, Okla. 78.
- silage, prairie hay, alfalfa hay, and cottonseed hulls, comparison for calves, Okla. 78.

Kalanchoe in cloth-covered enclosures, effects, 49.

Kale powdery mildew in Virginia, U.S.D.A. 343.

Kansas College, notes, 287, 895.

Kansas Station, notes, 895.

Karakul sheep, breeding, 677.

Karaya gum in nicotine sprys, 511.

Kelp-fish meal preparation, effect on reproduction in cows, N.J. 532.

Kelp meal feed, effect on iodine content of eggs, 681.

Kemp fibers in fleece of Scottish Mountain Blackface sheep, 35.

Kentucky Station, notes, 143, 432.

Kentucky Station, report, 894.

Kerosene cook stoves, economical management, Me. 141.

Kerosene-pyrethrum extract, use, Mass. 815.

Kidney—

pulpy, disease of lambs, 399, 848.

worm of carnivores in a mink, 253.

Kitchen arrangements, efficient, Ind. 893.

Kitten, hairless, with short tail and doglike habits, 608.

Knapp, S. A., life and work, 128.

Kudzu as temporary grazing crop, Ga.Coastal Plain 78.

Kumri of horses, etiology, 702.

Labor—see also Agricultural labor.

costs for man, horse, and machinery, Ill. 410.

distribution and costs in Idaho creameries, Idaho 111.

income and rate earned by farmers, Okla. 116.

incomes of farmers, effects of diversification, Wis. 551.

Lacebug on *Ocotoneaster*, Ohio 658.

Lacon variabilis, notes, 106.

Lactation—

in hypophysectomized guinea pigs, effect of thyroxine and galactin, 321.

in hypophysectomized guinea pigs, initiation and maintenance, 179.

physiology, 321.

relation to adrenotropic principle of pituitary, 179.

unknown factor essential for in oats and cottonseed oil, Ill. 419.

Lactic acid—

bacteria, vitamin and nitrogen requirements, 94.

fermentative production, use of agricultural products, Iowa 147.

in butter, determination, [N.Y.]Cornell 442.

in silage, determination, 745.

Lactobacillus—

casei cultures, nitrogen metabolism in Cheddar cheese, Iowa 230.

gas-producing species, 535.

Lactochromometer, development, 689.

Lactoflavine—

administered orally and parenterally, growth-promoting activity, 571.

cane v. beet molasses as source, 830.

in milk, human and cow's, 424.

in treatment of canine blacktongue, 571.

Lactose, bone-calcifying properties, Ill. 419.

Lamb—

curing methods, Okla. 78.
grading and stamping under Government inspection, U.S.D.A. 81.
vitamin B₁ and vitamin G in, S.Dak. 138.

Lamb—

dysentery serum, efficiency, 250.
sickness, Morton Mains, cobalt in treatment, 392.

Lambs—

crossbred, wool production and market value, Wyo. 80.
dipping for ticks, Wyo. 81.
dry-lot summer rations for, Nebr. 674.
effect of retarded growth on meat flavor and other characteristics, 673.
ewe, wintering on native hill pastures and in lowlands, 834.
fat, abomasal parasites in, 701.
fattening, corn and alfalfa hay rations for, Nebr. 674.
fattening, deferred grain feeding for, Idaho 826.
fattening, rations for, Okla. 78.
fattening, response to phosphorus supplements, Idaho, 826.
feed lot, shearing, Idaho 826.
feeding entirely in panels, Wyo. 81.
feeding experiments, Wyo. 80.
feeding in Indianapolis area, 673.
feeding in Michigan, cost records, Mich. 808.
grain for, Ind. 374.
growing, relative efficiency of various proteins for, 526.
hays in winter ration, comparison, Wyo. 80.
hothouse production, Pa. 79.
late native, fattening, 673.
leapedeza as fall pasture for, Ill. 374.
native, production, Ind. 834.
parasitic examination, Ohio 695.
phosphorus sources, cottonseed meal v. bonemeal, Idaho 826.
poorly nursed, suitable rations, Ind. 374.
production costs, Ky. 886.
quality, effect of feed, 673.
self-feeding v. hand-feeding of concentrates, Wyo. 80.
shorn v. unshorn, gains, finish, cost, and profit from, Ind. 374.
skins of, seasonal variations with reference to sudoriferous glands, 677.
spring, production, Idaho 826.
stiff, diagnosis, Wyo. 101.
temporary forage crops for, comparison, 673.
vitality and growth rate, relation to birth weight, Mass. 827.
western, fattening, Ind. 375.
western, feeding, Ohio 674.
winter rations, Ohio 674.

Land—*see also* Farm land.
agricultural, management and use, U.S.D.A. 707.
and water relations, effect of vegetation, U.S.D.A. 707.

Land—Continued.

classification, Me. 110.
classification in Wisconsin, 588.
classification method, 158.
classification program for Oregon, 119.
credit, *see* Agricultural credit.
Division of the Ministry in Great Britain, report, 414.
forest, *see* Forest lands.
grant colleges, *see* Agricultural colleges.
improvement measures, relation to beet leafhopper and curly top disease, U.S.D.A. 220.
in Panama, proposed distribution to poor farmers, U.S.D.A. 117.
legislation, Danish, recent trends, U.S.D.A. 117.
net value and management, Ill. 302.
of Willamette Valley, adaptability, Oreg. 264.
ownership, German, tightening of legislation, U.S.D.A. 551.
Planning Committee, supplementary report to National Resources Board, 411.
policy, national, bibliography, Calif. 552.
resources of Nebraska, conservation, 257.
settlement and unemployment, 711.
settlement as social problem, 414.
settlement in Germany, 414.
slope and utilization, Me. 110.
tenancy changes on small holdings, 712.
tenure in Chile, U.S.D.A. 117.
tenure law, new, in Colombia, U.S.D.A. 552.
tenure, National Farm Institute symposium on, Iowa 555.
tenure problem in Oklahoma, Okla. 867.
tenure, racial factors and economic forces in South, 268.
tenure, relation to agriculture, 711.
transfers in Cass County, North Dakota, N. Dak. 118.
use, adjustment, problems in, Ohio 551.
use, agricultural, adjustments, economics of, Iowa 552.
use and physical features in United States, graphic summary, U.S.D.A. 714.
use and recreation in Washington County, R.I. 877.
use control in Oklahoma, rural zoning as means, Okla. 116.
use, effect on rural social welfare, Ill. 417.
use in Antigonish County, Nova Scotia, 871.
use in Genesee County [N.Y.] Cornell 870.
use in Mecosta County, Mich. 714.
use in northern Minnesota, type study, 714.
use in southwest central Saskatchewan, 871.
use in Washington and Kent Counties, R.I. 870.

Land—Continued.

- use of problem areas in North Dakota, 124.
 - use problems, variations in soils complicating, Ill. 302.
 - use, proper, agricultural adjustment program based on, 614.
 - use suggestions for Ohio, Ohio 867.
 - use survey of Alberta, objectives in, 411.
 - use survey of Britain, land classification scheme of, 158.
 - users not conforming to zoning plan, savings in public expenditures by relocation, Wis. 551.
 - values and improved roads, 872.
 - worn-out, improvement for pasture, 672.
- Landslides, analysis and control, 164.

Laphygma frugiperda, see Armyworm, fall.

Larch—

- canker, European, in United States, 649.
- canker, European, relation to cankers of conifers in United States, 649.
- disease, history and literature, 649.
- in Hudson Highlands, terminal growth, 51.
- sawfly parasites, 359.

Lard—

- American, competitive position in foreign markets, Iowa 200.
- softness, variations in, 466.

Lariophagus distinguendus, parasitic on *Sitotropa panicea*, 507.

Laryngotracheitis—

- and allied respiratory diseases of poultry, [Conn.] Storrs 538.
- infectious, review, 704.
- infectious, studies, N.J. 546.
- infectious, virus, infectivity for developing eggs, 253.
- of chickens, control, Ill. 390.
- vaccination against, 703.

Lasioderma serricorne, see Cigarette beetle.

Latrodectus mactans, see Spider, black widow.

Lawn pests and diseases, control, R.I. 771.

Lawns, available nutrients in, 45.

Lead—

arsenate—

- acid, effect of ferric oxide on, 507.
- and oil combination, increased effectiveness, Ill. 359.
- brands, lack of variation in efficiency, Ill. 359.
- dusts, adherence and rate of settling for autogiro and airplane application, 509.
- effective substitutes for, Del. 218.
- in soft and hard waters, effect of soaps on formation of soluble arsenic from, 810.
- spray combinations, new, use, 658.
- sprays, stickers and spreaders used in, 509.
- substitutes, 72; Conn. [New Haven] 657; Mass. 814.
- summer oil for codling moth control, 510.

Lead—Continued.

- residue on apples, variability, 69.
- spray residues on Iowa-grown fruit, 217.

Leaders in Tennessee listed in Who's Who, losses and gains of, Tenn. 559.

Leaf—

- area, apparatus for measuring, Pa. 26.
- casebearer, control with parasites, 670.
- rollers and tiers, control, Ill. 359.
- tissues, carbohydrates in, effect on energy of photosynthesis and respiration, 168.

Leaf-footed bug, notes, Fla. 65.

Leafhopper genitalia, methods in study and preservation, 359.

Learning ability in rats, inheritance, 708.

Leaves—

- amylolytic activity, 166.
- green, availability of carbohydrates and fats, 585.
- green, availability of proteins and inorganic salts, 722.
- mutilated, in monocotyledons, regeneration from, 764.
- purine nitrogen in, determination, Conn. [New Haven] 580.
- water relations, effect of potassium supply, 763.

Lebia spp., notes, 822.

Lecithin—

- physicochemical studies, Minn. 581.
- synthesis in hens on vitamin A- and lipid-free diet, Fla. 78.

Legume—

- bacteria, activities in acid soils, Iowa 157.
- bacteria, behavior in relation to exchangeable calcium and pH of soil, Mo. 590.
- bacteria, longevity in water, 31.
- green manures, residual effect, La. 614.
- inoculants, inspection, N.J. 480.
- seed on acid soils, effect of fine limestone applied in row, 595.
- seedlings, effect of bios, 760.
- studies in pasture improvement, 163.
- testa, anatomy, relation to hard seed problem, 463.
- winter cover crops, La. 614.

Legume-lime system, relation to potassium needs of soil, Ill. 302.

Legumes—see also Green manure and Alfalfa, Clover, etc.

- adaptation studies, Okla. 39.
- causes of failures, Okla. 39.
- composition, relation to growth and maturity, Fla. 38.
- culture experiments, Okla. 39.
- experiments, Fla. 38.
- for green manure, tests, Iowa 180.
- for renovation of old bluegrass pastures, Wis. 474.
- inoculation—see also Nodule bacteria.
- tests of commercial cultures, Iowa 180.
- new seedlings, on acid soils, Iowa 157.

Legumes—Continued.

- nodulation, factors affecting, Ill. 324; Wis. 437.
- seedling stands, effect of damping-off fungi on, Iowa 200.
- soil-building, relation to peach insect control problem, Ill. 359.
- tests for hay and pasture, Iowa 180.
- variety tests, Alaska 770; Idaho 770; P.R.Col. 771; S.C. 39.

Leis dimidiata var. *trispilota*, introduction and propagation, Fla. 65.

Lema trilineata, see Potato beetle, three-lined.

Lemon—

- cuttings, rooted, transpiration, effect of humidity, 193.
- endoxerosis or internal decline, Calif. 805.
- endoxerosis, relation to amounts of irrigation water, 62.
- trees, gum from, 4.

Lemons—

- Eureka and Lisbon, bud selection and progeny tests, U.S.D.A. 48.
- Perrine, ascorbic acid in, 730.

Lentin, new rapid-acting cathartic for horses, 400.

Lepidiotia caudata, pest of pastures in Queensland, 823.

Lepidoderma albobirtum, notes, 106.

Lepidoptera, fruit-piercing, in Sierra Leone. 221.

Lepidosaphes—

- beckii, see Purple scale.
- ulmi, see Oystershell scale.

Leptinotarsa decemlineata, see Potato beetle, Colorado.

Leptocoris trivittatus, see Boxelder bug.

Leptoglossus phyllopus, see Leaf-footed bug.

Leptosphaeria sacchari, notes, 643.

Leschenaultia emul, biology, 518.

Lespedeza—

- as honey plant, 669.
- byproducts for feeding chickens, Ky. 827.
- chemical composition, Ky. 827.
- culture experiments, Ga.Coastal Plain 38; Tenn. 325.
- fertilizer experiments, Ga.Coastal Plain 38; Tenn. 325.
- hay v. alfalfa hay for feeding catilo, Ill. 374, 383.
- reestablishment in sod, S.C. 39.
- straw in winter ration of dry cows, Ill. 374.
- variety tests, Ga.Coastal Plain 38; Ky. 771; La. 614; Okla. 38; Tenn. 325.

Lespedeza sericea—

- as temporary grazing crop, Ga.Coastal Plain 78.
- culture experiments, Ga.Coastal Plain 38; Tenn. 325.
- cutting tests, Tenn. 325.
- dried leaves, vitamin G in, Tenn. 418.
- notes, La. 614.
- seed treatments and seeding tests, Tenn. 325.

Lespedeza sericea—Continued.

- selection for tannin, Tenn. 325.
- tests, Ind. 325.
- vitamin A in, Tenn. 418.

Lettuce—

- anthracnose in California, U.S.D.A. 343.
- cost of production, U.S.D.A. 261.
- effect of length of day, 761.
- head, breeding, Pa. 44.
- head, time of planting, N.Mex. 180.
- seed, dormancy, 45.
- seed, light-sensitive, germination, 169.
- tipburn resistant, breeding, 482.
- varieties, Mass. 782.
- varieties grown in England, classification, 482.
- variety tests, Pa. 44; R.I. 783.

Leucocytozoon, catalog and host index, 657.

Leucosin changes under action of flour and yeast proteinases, 439.

Leucosis—

- fowl, incidence in hatching eggs, 106.
- fowl, transmission experiments, 856.
- in poultry, importance, 703.
- studies, R.I. 856.

Leukemia—

- and allied conditions, etiology, Fla. 546.
- and fowl pox, pathogenic effect, differential diagnosis, and control, 704.
- etiology, Fla. 90, 254.
- in mice, malignant lymphocytes from perivascular reticular cells, 466.
- of fowls, Ill. 254.
- types, phagocytic activity of circulating cells in, 850.

Lerua iridescens, biological control, 823.

Lichen, ground, poisonous constituents in, Wyo. 101.

Lichens on fruit and nut trees, control, 503.

Light—see also Sunlight.

- action on germination of light-arrested fruits of Gramineae, 169.
- artificial, effect on flower formation and pollination in tomato, 482.
- artificial, effect on plant growth, 508.
- effect on sexual cycle of game birds, 471.
- factor in physiological processes, 26.
- from different parts of spectrum, physiological effects, 761.
- sexually stimulating, avenue of reception, 611.
- supplementary, for greenhouse plants, types of lamps, 45.
- traps, types, reaction of corn carworm to, 360.

Lights for egg production, Wyo. 81.

Lignin—

- chemistry of, 5.
- decomposition, 165; Iowa 157.
- of alfalfa meal, digestion trials with hens, 231.

Ligyris gibbosus, see Carrot beetle.

Lilac species and varieties, relative susceptibility to *Microsphaera alni*, U.S.D.A. 343.

Lilies, germination and seedling production, 341.

Lily—

- Easter, forcing by low temperature treatment, Fla. 43.
- Easter, pollination and seed setting, Fla. 43.
- mosaic virus, classification, 198, 355.
- Philippine, serious blight of, U.S.D.A. 198.
- pollen, longevity, 490.

Lima beans, *see* Beans, lima.Lime—*see also* Calcium and Liming.

- agricultural, analyses, N.J. 454.
- and potash relations, Tenn. 302.
- importance in Oklahoma, Okla. 13.
- rate of penetration on permanent sod, N.J. 473.
- requirements of soils, *see* Soils.
- soils, high, character, fertilization, and management, Iowa 158.

Lime (fruit)—

- tree looper, Conn.[New Haven] 813.
- trees, Tahiti, bark disease, Fla. 54.

Limequats, ascorbic acid in, 730.

Limestone—

- amount and depth of application, effect on alfalfa, [Conn.] Storrs 473.
- degree of fineness, important factor in dry mix fertilizer, 595.
- degrees of fineness, relative value, Pa. 13.
- in rations for fattening calves, Ind. 374.

Lime-sulfur—

- sprays, effect on respiration rate of apple leaves, 337.
- substitutes in summer sprays for orchards, Mass. 814.

Liming—

- Coastal Plain soils, Va. Truck 309.
- problems, Tenn. 302.

Limonius—

- californicus*, *see* Sugar beet wireworm.
- ectypus*, *see* Wireworm, eastern field.

Lincodes integra, potential pest of greenhouse tomatoes, 515.

Linfield, F. B., retirement, editorial, 1.

Linkage—

- data on albino chromosome of mice, 36.
- relation of genes in rabbits, 466.
- studies with rats, 468.

Limnodynastes antennae, notes, 815.

Linsced meal proteins, value for lambs, 526.

Liothrips varicornis in California, 512.Lipase production by *Penicillium oxalicum* and *Aspergillus flavus*, 148.

Liquid films, flowing, measuring thickness, 238.

Listerella—

- hepatolytica* n.g. and sp., proposed name, 696.
- infection associated with meningoen- cephalitis in sheep, 398.
- pathogenic organisms of genus, 696, 697.

Listroderes obliquus, *see* Vegetable weevil.*Litargus balticatus*, notes, Hawaii 99.

Orchards—see also Fruits, Apples, Peaches, etc.

- culture, Wis. 480.
- fertilization, Wash. 333.
- Illinois, oil sprays safe for, Ill. 359.
- irrigation, Wash. 333.
- management, U.S.D.A. 190.
- soil management, Can. 783; Ind. 332.

Orchards—Continued.

soil management, effect on tree growth, Ohio 484.

spraying, N.J. 506.

studies at United States Dry Land Field Station, Ardmore, S. Dak., U.S.D.A. 286.

water for, storage, pumping, and distribution, 259.

winter injury in Pennsylvania and adjoining States, 784.

young, fertilizers for, Tenn. 333.

Orchestes pallicornis, see Apple flea weevil.

Orchestia platensis, notes, Hawaii 99.

Organic matter—

in orchard soils, effect of culture, Md. 624.

in soils of Coastal Plain, Va. Truck 752.

in soils, peat bogs, and composts, chemical nature, 450.

in soils, restoration, Nebr. 587.

incorporating with soil, methods, Mo. 22.

maintenance, Wash. 302, 325.

value and decomposition in soils, N.J. 447.

Organisms, see Bacteria and Micro-organisms.

Oriental beetle, studies, Conn. [New Haven] 657; Hawaii, Sugar Planters' 319.

Ornamental plants, shrubs, and trees, see Plants, Shrubs, and Trees.

Ornithodoros—

hermsi, progress of spirochaete infection in, 245.

turicata, vector of relapsing fever, 671.

Ornithogalum bulbs, root knot nematode on, 808.

Ornithostrongylus—

crami and *O. faria*, synonymy, U.S.D.A. 859.

quadriradiatus, parasite of domesticated pigeon, U.S.D.A. 859.

Orthoptera—

ecological study of Chicago area, 661.

of South Dakota, additions to Hebard's list, 219.

Oscinella—

frit, see Frit fly.

Nearectic species, synopsis, 518.

Osmotic pressure and water relations of plant cells, 167.

Ontartagia circumcincta, notes, 701.

Otters, raising in captivity, U.S.D.A. 652.

Ova and blastocysts, mammalian, sectioning, technic, 611.

Ova, tube-locking by oestrogenic substances, 769.

Ovarian grafts, genetics of, 768.

Ovariectomy during gestation, effect, 769.

Ovaries of immature rats, response to injections, 179.

Ovens used for domestic cooking, studies, Ind. 734.

Ovulation—

and oestrus in mares, 319.

development of follicles in ovaries preceding, Wis. 469.

in fowls, mechanics, 770.

Oxidations, biological, studies, 582.

- Oryza chinensis*, notes, Hawaii 90.
Oxydema fusiforme, notes, Hawaii 90.
 Oxygen consumption, effect of coffee and decaffeinated coffee, 182.
Oxytetracycline parvovirus, notes, 656.
Oxythrips—
 coloradensis n.sp., description, 601.
 pinicola n.sp., description, 661.
 Oyster drill control, costs and profits in, N.J. 507.
 Oysters, research, N.J. 506.
 Oystershell scale, control, 818; Ill. 360; Mont. 66.
 Ozone, atmospheric, conference on, 11.
Ozonium omnivorum root rot in shelter-belt zone of Texas, 345.
 Paleobotany, 166.
 Palm leaf miner, major pest of palms in Florida, 820.
 Palm oil, dietetic value, 279.
Palorus ratzeburgi, notes, Hawaii 90.
 Pangenesis, hypothesis, 765.
 Pangoninae of Utah, 518.
Papaipema nebris nitela, see Stalk borer.
 Paper milk containers, N.Y. State 242.
Paraoecia new genus, description, 066.
 Paradichlorobenzene-treated coin, effect of feeding to swine, 701.
 Paralysis—
 fowl—
 and scrapie in sheep, comparison, 391.
 breeding for high and low resistance to, Mass. 827.
 etiology, Fla. 90, 254, 546.
 importance of endotoxin of *Salmonella aertrycke* in, 547.
 in Austria, etiology, 703.
 Marek's, 703.
 resistance of flocks to, establishment, Idaho 848.
 studies, 703; N.J. 546; Ohio 695.
 transmission experiments, 547; Ind. 390.
 infectious bulbar, see Mad itch and Pseudorabies.
 of chicks and vitamin B₁ deficiency, differentiation, 838.
 posterior, in swine, 400.
 range, etiology and transmission, Iowa 253.
 studies, [Conn.] Storrs 538.
Paramphistomum—
 cerri in alimentary tracts of goats, 399.
 cotylophorum, parasite of Trinidad deer, 213.
Parascatella new genus, description, 667.
 Parasite shipping cages, use of agar-sugar preparation as food in, 216.
 Parasites—
 and host relations, physiology, 342.
 animal, of animals and of man, 362.
 coccid-inhabiting, from Africa, descriptions, 520.
 endoglobular bovine, exposure to different degrees of temperature, 245.
 Parasites—Continued.
 insect, and predators, biological relations to their hosts, 216.
 insect, and predators, introduction and use, 216.
 intestinal, in wild rats, 245.
 of dogs, 252.
 of injurious insects, distribution, map and photographs, 670.
 of sheep, control, 106.
 of sheep, life histories, Calif. 250.
 Parasitism, intestinal, diagnosis and treatment, 244.
 Paratetranychus—
 alpinus on incense cedar, 521.
 pilosus, see Red mite, European.
 Parathyroid and thyroid in birds, antagonism, 681.
 Paratrichia cockerelli—
 biological control, Utah 67.
 culture methods for, 358.
 in southern California, life history, 359.
 in Wyoming, Wyo. 602.
 on tomatoes in Texas, 359.
 Paratuberculosis, see Johne's disease.
 Paratyphoid—
 in fowls, 108.
 in pigeons, 703; Ky. 848; N.J. 546.
 in turkeys, 858; Idaho 848.
 in young pheasants, Mass. 856.
 Parrenomates incerta n.sp., notes, 216.
 Paris green—
 homologs, 68.
 homologs, relative effectiveness against confused flour beetle, 812.
 Parorchis acanthus, experimental studies, 245.
 Parthenocary induced by pollen extracts, 171.
 Partridge-pea weevil, biology, 668.
Passalus cornutus, see Horned passalus.
Pasteurella—
 avida, cultural forms, immunogenetic value, 703.
 boriscripta in blood of Florida cattle, significance, 542.
 cuniculoida in domestic rabbits, 540.
 septica, immunization against, 395.
 spp., inoculation into developing eggs, pathogenicity, 104.
 Pasteurization—see also Milk.
 increasing use, educational work as factor, 847.
 Pastry, bread, and cake, home-made, recipes, U.S.D.A. 882.
 Pasture—
 and forage crops, symposium, 776.
 contest, annual, of Nebraska, 614.
 crops, winter, tests, Tenn. 325.
 effect on fat color in carcasses, Ill. 374.
 grasses, see Grasses.
 mixtures, S. Dak. 91.
 practices, successful, 614.
 research literature, digest, U.S.D.A. 326.
 system, all-year, for Missouri, Mo. 474.

Pastures—*see also* Grasses, Grassland, and Meadows.

- bluegrass, renovation, relation to white grub populations, 667.
 - botanical composition, soil properties determining, 750.
 - Coastal Plains, beef-producing capacity, effect of treatments, S.C. 79.
 - cut-over, developing, Mich. 618.
 - effect of fertilizer treatments, [Conn.] Storrs 473; Ia. 236.
 - effect of fertilizers and grazing, Iowa 180.
 - emergency project in northern Minnesota, 832.
 - experiments, Tenn. 325.
 - fertilized, carrying capacity, N.J. 532.
 - fertilizer experiments, Ind. 325.
 - for hogs, comparison, Ky. 827.
 - grazing, continuous v. alternate with heifers, Ky. 827.
 - improvement, 163; Del. 180; Ill. 383; Iowa 180.
 - increased use, 672.
 - irrigated, commercial fertilizers for, Utah 13.
 - lowland and upland, returns from, Ga. Coastal Plain 78.
 - management, Nebr. 614; Okla. 78.
 - management research, Wis. 474.
 - necessity in economic lamb production, Ind. 374.
 - permanent, acreages, Iowa 260.
 - permanent, renovation, Wyo. 40.
 - plant population at Beltsville, Md., U.S.D.A. 229.
 - renovation, relation to white grubs, 618.
 - research procedure, 672.
 - ridding of *Taenia saginata* ova by grazing cattle or sheep, 101.
 - studies, Fla. 38; Ky. 771; La. 473; Mass., 771; N.J. 473; S.C. 688; Wyo. 40.
 - supplementing for milking cows, Ohio 687.
 - treating to prevent erosion and run-off, Iowa 157.
 - uses in southern Indiana, Ind. 410.
 - value for fattening pigs, 672.
 - yields, determination through actual grazing, Wis. 474.
 - yields, determining by grazing and clipping, 777.
- Pavement concrete, strength and uniformity, effect of vibration, U.S.D.A. 257.

Pea—

- aphid control in Maryland, 513.
- aphid, control with derris and cube, U.S.D.A. 215; Wis. 506.
- aphid damage to canning peas, Utah 67.
- aphid, notes, Me. 66.
- aphid, relation to clover and alfalfa failure, Ky. 814.
- cannery refuse, Wash. 383.
- diseases, new in Wisconsin, Wis. 493.
- diseases, virus, Wash. 344.
- germ meal as source of vitamin E, Idaho 839.

Pea—Continued.

- mosaic diseases and *Fusarium* wilts, Idaho 794.
- mosaic diseases in Washington, 490.
- mosaic on Long Island, U.S.D.A. 636.
- mosaic, studies, 802.
- mosaic virus 2, transmission by aphids, 514.
- mosaic viruses, comparison, 343.
- moth studies, Wash. 361.
- root rot in Wisconsin, U.S.D.A. 636.
- root rot, notes, N.J. 493.
- seed protection by mercury dust compound, 57.
- seed, red copper oxide and graphite application to, method, 642.
- seed treatment, 642.
- seed treatment, effect on nodulation by *Rhizobium leguminosarum*, Ill. 602.
- seeds, fungus associates of, 499.
- streak, relation to strains of alfalfa mosaic, 198.
- weevil, control, Idaho 813.
- weevil control, plow development for, Idaho 860.
- weevil, growth, effect on weight and germination of seed peas, 823.

Peach—

- aphid, green, notes, 801.
- aphid, green, reaction to colored insecticides, 364.
- bacterial spot, reducing damage from, Ill. 343.
- borer control, value of liquid paradichlorobenzene in, Ill. 359.
- borer, lesser, notes, Del. 215.
- borer moths, flight and movement, 65.
- buds, types, relation to nursery practice, 629.
- cankers, U.S.D.A. 794.
- diseases, effect of water-table levels, 61.
- insect control problem, relation to soil-building legumes, Ill. 359.
- insects, new oil dusts for, value, Ill. 359.
- leaf curl, control, 352.
- little disease, dissemination by *Macropis trimaculata*, Del. 199.
- little disease, masking in plums and other *Prunus* species, Del. 199.
- mildew, frosty, 804.
- mosaic, control, 503, 638; Utah 54.
- mosaic, eradication, 794; U.S.D.A. 343.
- mosaic, identification and control, U.S. D.A. 352.
- orchards, soil management, Okla. 44.
- phony disease, control, 638; U.S.D.A. 343.
- phony disease, status, Ky. 794.
- roots, distribution in different soils, Ohio 623.
- roots, nematodes affecting, 61.
- scale, West Indian, on papaya, control, P.R.Col. 814.
- seeds, viability, method for determining, 338.
- sprays, Conn.[New Haven] 813.
- stone fungus *Caryospora*, life history, Md. 637.

Peach—Continued.

- trees, effects of mineral deficiencies, N.J. 480.
- trees, fertilization, 339.
- "X" disease, Conn.[New Haven] 636.
- yellows, dissemination by *Macropsis trimaculata*, Del. 199.
- yellows, incubation period in its insect vector, 504.
- yellows, intracellular bodies associated with, movement, 107.
- yellows, masking in plums and other *Prunus* species, Del. 199.

Peaches—

- adaptability in Wichita Valley, Tex. 46.
- breeding, Ill. 336; N.J. 480.
- breeding hardier varieties, Iowa 189.
- bridge-grafting, Mich. 333.
- brushed and nonbrushed, infection studies with *Sclerotinia fructicola*, 62.
- canned clingstone, f. o. b. prices, analyses, Calif. 557.
- cause of one half larger than the other, N.Y.State 192.
- culture, Mo. 192.
- deterioration, reduction by proper refrigeration, Ill. 410.
- Elberta, shoots, seasonal course of soluble nitrogen and phosphate phosphorus, Ky. 336.
- embryo abortion, relation to chemical composition and season of fruit ripening, 629.
- fertilizers for, Ill. 336.
- fruit development, varietal differences, 339.
- genetic composition, Mass. 782.
- grapes, and plums, comparative resistance to winter colds, Ohio 628.
- growth, Del. 186.
- growth, three periods in fruit, N.Y.State 786.
- harvesting, packing, and storing, Wash. 333.
- market diseases, U.S.D.A. 203.
- packing, reducing costs in, Ill. 410.
- Phillips Cling, gumming, control by delayed thinning, Calif. 630.
- precooling in refrigerator cars, Ind. 403.
- production in Ohio, Ohio 630.
- pruning, Md. 624.
- quality, relation to time of picking, Ill. 336.
- resistance to low temperatures, N.J. 480.
- rootstocks for, N.J. 480.
- seed attachment and carpel symmetry and development, relation, 48.
- spray injury, U.S.D.A. 636.
- summer-oil emulsion tests, 811.
- thinning, Ill. 336.
- varieties, Ind. 332; Okla. 44; S.C. 44.
- varieties, desirable, Utah 44.
- varieties, new, 786; Tenn. 333.
- variety tests, La. 186; Wash. 333.

Peacocks, chromosomes in, morphology, 464.

Peanut—

- hay and cowpea hay as feed for sheep, comparison, 834.

Peanut—Continued.

- hay, feeding value, Fla. 78.
- meal, feeding value, Tenn. 375.
- oil, vitamin B₁ in, 135.
- plant, nutritional levels in, 184.

Peanuts—

- as basal ration for swine, deficiencies, Fla. 78.
- breeding, Fla. 37; Ga.Coastal Plain 38.
- culture experiments, Ga.Coastal Plain 38.
- culture under dry land conditions, N.Mex. 475.
- fertilizer experiments, Ga.Coastal Plain 38.
- increased yields through insect control, 507.
- Spanish, v. other grazing crops for pigs, Fla. 78.
- variety tests, Ga.Coastal Plain 38; La. 614; P.R.Col. 771.

Pear —

- bitter pit and related diseases, Wash. 344.
- fire blight, control, Wash. 333.
- fire blight, inheritance of plant characters, 197.
- fire blight resistance, development, Ill. 336; Tenn. 333.
- fruit saw-fly in England, 77.
- midget control, N.Y.State 286.
- roots, nematodes affecting, 61.
- rootstocks, testing, Can. 783.
- rots, Wash. 344.
- slug, control, Mont. 66.

Pears—

- breeding, Iowa 180.
- in transit from Pacific Northwest during winter months, U.S.D.A. 486.
- Packham's Triumph, stem-end shrivel, 486.
- root systems, 628.
- unsatisfactory in Wichita Valley, Tex. 46.

Peas —

- and rye, costs involved in growing, Alaska 770.
- Austrian winter, as temporary grazing crop, Ga.Coastal Plain 78.
- Austrian winter, rotation experiments, Fla. 38.
- breeding, Tenn. 325; Wis. 480.
- canning, composition, effect of fertilizer and variety, Alaska 782.
- canning, damage by pea aphid, Utah 67.
- canning, quality and composition, effect of fertilizer, 45.
- canning tests, Md. 624.
- canning, varieties and fertilizer requirements, Alaska 782.
- effect of cyanamide applied December 1 on subsequent crops, Md. 625.
- effect of length of day, 761.
- flat, composition and apparent digestibility, Wash. 383.
- green, vitamin G in, Tenn. 418.
- high-speed combines, and reel and bunching equipment for, Idaho 800.

Peas—Continued.

seed treatment with Semeran, Wyo. 53.
summary of studies, La. 624.
variety tests, Idaho 770; Pa. 41; S.C. 44.

winter, culture experiments, Okla. 30.
winter, variety tests, Okla. 38.

Peat—

and muck soils, pasture studies, Fla. 38.
areas in Pacific Coast States, U.S.D.A. 14.

boas, organic matter in, chemical nature, 450.

ionic relations in, 451.

lands, crop yields on, effect of depth of ground-water level, Minn. 862.

sawgrass, studies, Fla. 13.

soils, best practices for, Utah 13.

soils, uniform fields of carrots and onions on, 334.

soils, water control on, Fla. 109.

Pecan—

buds, morphological development, 633.

bunch disease, 196, 504.

groves, soil management, Okla. 44.

rosette, control, 504.

rosette, effect of zinc sulfate, Fla. 43.

shuck worm, control with parasites, 670.

trees, insects affecting, Fla. 65.

trees, transplanted, effects of root pruning, 633.

Pecans—

cover crops for, Fla. 43.

disporous *Gnomonia* on, 209.

fertilizer requirements, Fla. 43.

food storage and growth, relation to nitrogen absorption, Fla. 43.

varieties, N.Mex. 186.

varieties and propagation, Okla. 44.

varieties, extraction of oil from kernels, Fla. 43.

variety response to soil types, Fla. 43.

variety tests, La. 186.

Pectase and rennin reactions, mechanism, similarity, 438.

Pectic extractions from apple pomace, enzymatic hydrolysis of starch in, Del. 147.

Pectin—

in avocado leaves, 600, 632.

relation to jelly making, progress in research on, 880.

role in fruit jellies, Del. 4.

Proctophora gonypipella, see Bollworm, pink.*Pediculoides ventriosus*, see Straw itch mite.

Pellagra-preventing factor and vitamin G in chicks, differentiation, 233, 234.

Penicillium—

mold on citrus, control, Fla. 53.

ovaleum, lipase production by, 148.

roqueforti, action on lower fatty acids, 847.

roqueforti, gas requirements, 846.

roqueforti strains, protein and fat metabolism in Iowa blue cheese, Iowa 236.

Pennsylvania College, notes, 143, 288, 432, 507

Pennsylvania Station, notes, 143, 288, 432.

Pennsylvania Station, report, 142.

Pentosan of alfalfa meal, digestion trials with hens, 231.

Peonies—

classification and nomenclature, Ill. 341.

varieties, Iowa 186.

Peony—

blooms, cutting methods, Ill. 341.

Cladosporium leaf blotch, cause of, 356.

Pepper—

maggot, notes, Conn.[New Haven] 813.

virus diseases, Fla. 54.

weevil, life history, host plants, and control, Fla. 668.

weevil, notes, Fla. 65.

Peppermint *Verticillium* wilt, 107.

Peppers—

breeding, Conn.[New Haven] 624.

cost of production, U.S.D.A. 261.

fertilizer requirements, P.R.Col. 783.

frost protection for, Fla. 12.

infection with tobacco-mosaic virus, inheritance of resistance, 499.

Perfection pimiento, root-stem transition region, anatomy and histology, 626.

summary of studies, La. 624.

sweet, preservation by salting and fermentation, Mass. 879.

Perilla meal, digestibility, Calif. 82.

Perilla ocyroides, development, effect of light induction on, 459.*Perillus bioculatus*, notes, 822.*Periplaneta americana*, see Cockroach, American.*Pezisotola*—

angulata, breeding, 358.

sp., parasite of pink bollworm, P.R. 664.

Permeability—

of ground, direct measurement, 404.

of soils, factors affecting, Nebr. 587.

relation to frost resistance and seasonal cycle, 312.

Peromyscus, inherited tremor in, 177.

Peronoplasmodium cubensis, notes, Fla. 53.*Peronospora*—

destructor, notes, U.S.D.A. 493.

effusa from spinach, germination of conidia, 196.

tabacina, control in tobacco plant beds, 196.

tabacina, early appearance in Georgia, U.S.D.A. 53.

tabacina infection and sporulation in tobacco seedlings, 197.

tabacina, notes, U.S.D.A. 493.

Perosis—

in chicks, 703.

in poultry, relation to nutrition, Pa. 79.

incidence and prevention, Okla. 79.

Peroxidase and ascorbic acid, interaction in biological oxidations and reductions, 583.

Persimmon *Cephalosporium* wilt, U.S.D.A. 636.

Pest control, patents relating to, U.S.D.A. 63.

- Petrography, value for determining quality of rock, U.S.D.A. 550.
- Petroleum—
 base insecticides, testing, modified procedure, 370.
 oil, chemical properties of unsaturates causing foliage injury, 57.
 oil unsaturates, properties causing injury to foliage, 660.
- Phalaenoides glycinac*, parasites of, biology, 826.
- Pheasant eggs, artificial incubation, Idaho 826.
- Pheasants—
 Caucasian and silver, chromosomes in, morphology, 464.
 effect of subzero weather of 1936, 655.
 food habits, 654.
 ring-necked, propagation, Pa. 79.
 ring-necked, protein requirement of chicks, 89.
 semidomesticated, ecology, Iowa 215.
 turkeys, ducks, and geese, comparative growth rates, 686.
 young, paratyphoid infection in, Mass. 856.
- Phenol and phenyl mercaptan, relative toxic action on goldfish, 69.
- Phenothiazine as insecticide, 658; U.S.D.A. 215.
- Phigalia titea* on cranberry, Mass. 815.
- Phlox blight, relation to noninfectious chlorosis, 198.
- Phlox, testing, N.J. 480.
- Phlyctaenia rubiginis*, see Greenhouse leaf tier.
- Phoma*—
 leaf spot and stem canker of snapdragons, U.S.D.A. 498.
terrestris on onion in Iowa, Iowa 200.
- Phomopsis citri*, notes, Fla. 54.
- Phosphatase—
 in milk, variations during progress of lactation, 240.
 serum, activity in fowls, 529.
- Phosphate—
 adsorption and displacement, N.J. 447.
 deficiency, effect on sugarcane, Hawaii. Sugar Planters' 780.
 fertilization, effect on amphoteric properties of Coastal Plain soils, 25.
 fertilizer mixtures, chemical changes and physical effects, 166.
 fertilizers, availability, methods for testing, 592.
 fertilizers, value, Ind. 302; Mont. 165.
 rock, availability, effect of limestone, Ky. 748.
 rock, availability in soils of varying degrees of acidity, 453.
 rock, effect on dairy cows, 672.
 rock, not substitute for limestone as non-acid-forming fertilizer, Ind. 302.
 rock, studies, Idaho 748.
- Phosphates—
 assimilability, blastomycetic method of determining, 763.
- Phosphates—Continued.
 availability in calcined phosphates and calcium metaphosphate, R.I. 749.
 effect on reproduction in rats, 567.
 migration, Tenn. 302.
 new, Tenn. 302.
 soil, solubility, effect of carbon dioxide, 453.
 under field and greenhouse conditions, comparison, Ky. 748.
- Phosphatic fertilizers, blast furnace processes for production, U.S.D.A. 452.
- Phosphoric acid, available in soils, determination, 150.
- Phosphorus—
 availability in alkaline soils, Nebr. 587.
 availability in Idaho soils, Idaho 748.
 carriers for tobacco and cotton, Ga. Coastal Plain 38.
 carriers, new, tests, Tenn. 325.
 compounds in rat tissues, effect of vitamin D and phosphorus in diet, 139.
 deficiency as cause of low gain in summer range cattle, Utah 80.
 deficiency for New Zealand livestock, 377.
 deficiency in sections of State, Idaho 826.
 in blood serum of horses, variations in, 545.
 in mineral mixtures, conformation to experimental findings, 673.
 in pasture herbage, effect of fertilization and liming, 776.
 in poultry ration, effect on egg production and hatchability, 530.
 in range forage, N.Mex. 228, 522.
 injury to oats in excess doses, 184.
 inorganic, role in calcification on cereal diets, 283.
 inorganic, state and partition in serum of fowls, 88.
 need for, Fla. 13.
 soil, effect of lime-legume treatment, Ill. 302.
 supplements for pigs, Ill. 678.
- Phosphotungstic acid method for determining ascorbic acid in urines, 153.
- Photoelectric cell use in plant investigations, bibliography, 26.
- Photoperiodism—see also Day length.
 and allied topics, 598.
 and artificial illumination of plants in winter, 168.
 and growth of tea plant, 168.
 inner daily rhythm as basis of reactions, 26.
 studies with short-day plants, 459.
- Photosynthesis—
 attempted theory, 167.
 Blackman reaction in, nature, 459.
 daily rate, of young apple tree, [N.Y.] Cornell 483.
 effect of carbohydrates in leaf tissues, 168.
 in alfalfa, relation to sulfur dioxide in air, 497.

Photosynthesis—Continued.

- in apple leaves, effect of water deficiency, 47.
- in green plants, 26.
- in plants, continuous measurement, 457.
- in woody plants, ecology, 701.
- rate as function of wave length of light, 313.
- time course, 458.
- use of radiant energy in, mechanism 168.

Phyllophaga—

- implioita*, studies, Iowa 215.
- spp. in pastures, control, 667.
- spp., notes, Del. 215.

Phymatotrichum omnivorum, penetration in cotton roots grown under pure-culture conditions, 198.*Physalospora obtusa* and *P. mutila* n.comb., notes, 804.Phytin, effect on metabolism of *Aspergillus niger*, 172.

Phytomonas—

- coronafaciens*, notes, 202.
- geranii* n.sp., description, 647.
- lactucae-scarioriae* n.sp. and *P. pruni*, comparison, 795.
- primulae* n.sp., description, 647.
- pruni* on soybeans, Del. 199.
- rhisogenes*, nitrogen metabolism, 494.
- rhisogenes*, notes, U.S.D.A. 194.
- rubrilineans*, notes, 643.
- solanacearum*, notes, Fla. 53; P.R.Col. 795.
- sp. on filberts, 807.
- stewartii*, bacteriophage inhibiting, Ohio 637.
- stewartii*, studies, Wis. 493.
- tabaci* toxin, nature of, Ky. 794.
- tardiorescens*, notes, 505.
- tumefaciens*, effect of enzymes and amino acids, 201.
- tumefaciens*, nitrogen metabolism, 494.

Phytomyza—

- atricornis*, synonymy, distribution, and biology, 74.
- chrysanthemi*, see *Chrysanthemum* leaf miner.

Phytophaga destructor, see Hessian fly.

Phytophthora—

- oocorum* trunk canker of apple, Ind. 343.
- infestans*, see Potato blight, late, and Tomato blight, late.
- root rot on strawberries, Ill. 343.
- rot of honeydew melon, 802.
- sp. on marigolds, 198.

Pickles, home-canned, antiscorbutic value, Me. 128.

Pie Flour Committee, report, 562.

Pleisma cinerea, transmission of a beet virus disease by, 196.

Pig ascarid eggs, development, 213.

Pigeon pox vaccine for control of fowl pox, Ill. 390.

Pigeonpeas—

- breeding, Fla. 37.
- variety tests, P.R.Col. 771.

Pigeons—

- in Canada, parasites of, 656.
- peroxidases and formation of hemoglobin in development, 682.

Pigmentation—see also Anthocyanin and Color inheritance.

- bacterial, studies, 597.
- irregular, among poultry, heritability, 681.

Pigments, plant, rapid determination, 597.

Pigs—see also Sows and Swine.

Pigs—Continued.

spring, rations after weaning, S.Dak. 79.

spring v. fall, Iowa 227.

use of oat meal feed in ration, 672.

warm dressed yield, relation to shrinkage and fill. Ind. 374.

weanling, rations for, Mo. 85.

Pigweed seed in ration for chicks, Nebr. 674.

Pilchard oil—

as source of vitamins for poultry, 680.

calcifying property, effect of charcoal and length of storage on, 684.

Piles—

distribution of stress around, 404.

lateral resistance, 404.

Pine—see also White pine.

beetle, Queensland, control, 824.

beetle, western, effect of subzero temperatures on populations, 519.

beetles, ecology and control in Great Britain, 824.

blister rust, see White pine blister rust.

forest, maturing, reduction in number of trees, 491.

in Hudson Highlands, terminal growth, 51.

loblolly, mortality and growth, effect of stand density, 196.

longleaf, forest soils, effect of frequent fires on profile development, 51.

longleaf, region, soil fauna associated with forest fires in, 210.

needle blight, disseminated by rain, effect of grass fires, 210.

poles, creosoted, decay in, relation to penetration, 651.

red, plantation, lysimeter studies, Conn. [New Haven] 753.

red, planting distances for, Pa. 50.

red, *Tympanis* canker of, 650.

root rot, studies, N.J. 493.

Scotch, seedlings, growth in pot cultures of different soils under varied radiation intensities, 635.

seed oil, vitamin B₁ in, 135.

shoot moth, European—

control, 659; Conn. [New Haven] 657.

in Sweden, 604.

winter mortality of larvae, 516.

stands, nonnormal loblolly, construction of yield tables, 491.

Pineapples—

development, origin and growth of leaves and inflorescence, 633.

varieties and mutant and hybrid derivatives, 768.

Pinus monticola, effect of early frosts in northern Idaho, U.S.D.A. 53.

Pip, contagious, in fowls, treatment with argyrol, 703.

Piperidine, penetration into bodies of insects, 360.

Pippin oil, vitamin B₁ in, 135.

Piroplasmosis—

etiological agent, effect of exposure to different degrees of temperature, 699.

treatment with akiron, 697.

Pissodes strobi, see White pine weevil.

Pistachio oil, vitamin B₁ in, 135.

Pitot tubes, transverse, characteristics, 250.

Pituitaries of young pigeons, absence of follicle-stimulating hormone in, 37.

Pituitary—see also Hypophysis.

adrenotropic principle, relation to lactation, 179.

anterior, experiments with laying hens, 680.

anterior, lactogenic preparation from, 321.

anterior, of female rats, morphologic reaction to injections of pregnancy urine extracts, 760.

extract, augmentary factor in animal sera after injections, 322.

extracts, injections into cows, effect on milk production, 321, 322.

glands of ewes in various phases of reproduction, Mo. 612.

glands of rat, galactin in, 322.

glands of rat, galactin in, effect of stimulus of suckling, 322.

glands of sheep, production of antibodies to gonadotropic hormones, 322.

grafts, genetics of, 708.

hormones, action on various parts of body, 470.

hormones, inhibition of action by animal sera, 322.

hormones, relation to growth of mammary gland, Mo. 612.

hormones, relation to ovulation, corpus luteum formation, and secretion, 613.

Plaesus javanus, predatory beetle of banana root borer, introduction from Fiji, P.R. 824.

Plagiorchis—

laricola in turkey poult, deaths from, 706.

app., life histories, 809.

Plagiorhynchus formosus in whitethroated sparrow, N.J. 546.

Plague among wild rodents, role in human epidemics, 105.

Planning—

and political geography, 413.

Board, Utah State, report, 413.

boards, State, review of activities and progress, 412.

Commission, New England Regional, accomplishments and recommendations, 268.

Committee, Land, supplementary report to National Resources Board, 411.

county, approach to, 268.

economic, for agriculture, research program, 412.

social, for Canada, 125.

State, field of, 125.

Planning—Continued.

State, in Oklahoma, compendium of maps and charts pertaining to, 124.

State, in Oklahoma, report, 124.

Planorbis pfeifferi, new cercariae from, 245.

Plant—

assimilation, dependence of growth on, 761.

breeding, *see* Heredity, Hybridization, and specific plants.

bug, Say's, control, Mont. 66.

cell wall growth and turgor stretching, optical tests, 762.

cells—*see also* Cell(s).

electrophoresis trials in interior, 167.

frost-hardening studies, 311, 312.

large, absorption of electrolytes in, 167.

water relations and osmotic pressures, 167.

chromosomes, *see* Chromosomes.

coleoptile, growth, effect of weak electric currents on, 460.

disease outbreaks, uncontrolled, progressive intensification, 64.

disease survey, Conn.[New Haven] 636; Iowa 200; P.R.Col. 795; Wash. 344.

disease survey in Massachusetts, U.S.D.A. 636.

diseases—*see also* Fungi and different host plants.

bacteria causing, 792.

control by resistant varieties, 793.

crop losses from, U.S.D.A. 492.

effect on variability of yields, 342.

in Arkansas, U.S.D.A. 492.

in Kentucky, U.S.D.A. 492.

in Ohio, U.S.D.A. 794.

in southern California, U.S.D.A. 53.

in United States, U.S.D.A. 198.

insect vectors of, need of permanent reference collections, 793.

introduction to research on, treatise, 791.

nonparasitic, and organisms, index, U.S.D.A. 198.

on Staten Island, N. Y., U.S.D.A. 53.

recent fluctuations in United States, 793.

seedling, in Midwest nurseries, U.S.D.A. 53.

typical, analysis from quarantine standpoint, 199.

virus, histology of necrotic lesions, 56.

virus, insect transmission, 650, 793.

extracts in animal nutrition, 376.

food, available, seasonal fluctuation in, N.J. 473.

growth—

and soil conditions, treatise, 538.

effect of day length and artificial illumination, 598.

hormone in shoots, production and distribution, 758.

Plant—Continued.

growth—continued.

hormones and mineral nutrition, 758.

hormones, mitotic and cell-stretching, 759.

hormones, role in production of intumescences on poplar leaves, 651.

promoting substances, use in propagation, Ohio 634.

relation to boron and iodine, Ky. 757.

relation to cations contained in adsorption complex, 160.

responses to temperature, 49.

substance, inactivation by light, 759.

vitamin B, as factor, 760.

inspection, *see* Nursery inspection.

material analysis, methods, Hawaii. Sugar Planters' 743.

material, ashing, improved method, 295.

materials, decomposition of lignin in, 165.

nutrition and animal nutrition, treatise, 878.

nutrition and subsoil structure, 164.

nutrition, relation to minor elements, 599.

pathogens, physiologic races, keys, Minn. 637.

pigmentation, *see* Anthocyanin, Pigmentation, and Pigments.

protection by disinfection, fumigation, and spraying, 217.

protection, scientific principles, treatise, 793.

quality, electrometric determination, 28.

residues, decomposition, associative and antagonistic relation in, 24.

seedlings, stimulation by organic matter, 599.

serology, critical review, 601.

stem and leaf anatomy, effect of supplemental light, 169.

stems, flowering, anatomical characteristics, 601.

stems, tissue development, relation to organ size, 762.

tissues, ascorbic acid in, state of, 426.

tissues, internal gases, determination, 596.

tissues, pH determinations, range indicator method, 596.

virus serology, limitations, 196.

viruses, identification in the field, 792.

Plantation operations of landlords and tenants, Ark. 555.

Plants—*see also* Vegetation.

and micro-organisms in soil, reciprocal influences, N.J. 447.

carbohydrates in, 744.

carbon dioxide assimilation, dependence on wave length of radiation, 313.

carbon dioxide exchange rhythm and fruitfulness, 333.

Plants—Continued.

- composition, relation to feeding value, 776.
- composition, variations in, interpretation in relation to feeding value, 829.
- development on peat and muck soils, role of zinc in, Fla. 13.
- diseased, physiology, 199.
- eaten by California mule deer, 653.
- electrical transport theory, 460.
- feeding power, relation to straw, Ill. 324.
- Florida, collection and preservation of specimens, Fla. 25.
- flowering, photoperiodic effects, Ohio 634.
- flowering, self-sterility in, cytological phenomena in, 174.
- grafted, and chimeras, disease relations, 637.
- green, nitrogen nutrition, 28.
- greenhouse, reaction to gas in atmosphere and soil, Mich. 758.
- greenhouse, supplementary light from lamp types, 45.
- growing, humidity- and temperature-control cabinet for, 473.
- heat treatment, portable chamber for, 31.
- higher, mitochondria in life cycles, 170.
- hydrogen sulfide injury to, 494.

- variety tests, R.I. 783; U.S.D.A. 190.
- winter injury, varietal susceptibility, Wash. 333.

Plutella maculipennis, see Diamondback moth.

Pneumococcal infections (type I) of rats, experimental work, 540.

Pneumonia, cevitic acid excretion in, 139.

Poa genus, cytological study, 606.

Podagricomela spp., notes, 372.

Podisus maculiventris, notes, 822.

Podosporella spp., causing decay in apples, 645.

Pogonomyrma barbatus, see *Ants*, red harvester.

Poinsettias—

grown in sand, 490.

importance of organic matter in potting soils, Mich. 625.

Poison-ivy, test of chemicals for, Ill. 324.

Poisoned bran bait for control of June beetle larvae in tobacco beds, Ky. 814.

Poisonous plants, see Livestock poisoning; Plants, poisonous; and *specific plants*.

Poisons, contact and stomach, organic compounds for, 360.

Poliomyelitis, experimental, vitamin C therapy, 137, 138.

Pollen—

extracts, parthenocarp induced by, 171.

grains, development, methods for study, 596.

production of anemophilous plants, 456.

substitutes for bees, 825.

tubes, growing, fixing, and staining, 596.

Pollination—see also *specific plants*.

and fruit setting, Mo. 190.

Polyphase phenomena, polygonal graphs for, 26.

Polyplody, physiological consequences, 176.

Polyporus schweinitzii—

causing root and butt rot in white pine, 650.

variability in culture, 650.

Polytictus versicolor, growth and carbon dioxide productions, factors in, 356.

Pomphopoea sayi, see Blister beetle, Say's.

Ponies, cottonseed meal as feed for, 672.

Popcorn—

breeding and culture, Iowa 181.

variety tests, Okla. 38.

Popillia japonica, see Japanese beetle.

Poplar—

growing for farm wood supply, R.I. 783.

leaves, intumescences on, 651.

sawfly, notes, Conn.[New Haven] 813.

yellow, merchantable in Appalachian region, decay in, U.S.D.A. 505.

Population, rural, movements, Ohio 720; S.Dak. 125.

Pork—

curing on the farm, Pa. 79.

oxygen uptake, factor in color, 380.

production, grazing crops for, Fla. 78.

production, treatise, 836.

quality, effect of soybeans and soybean products, Ind. 374.

Porosagrotis orthogonia, see Cutworm, pale western.

Porthetria dispar, see Gypsy moth.

Potash—

available, in commercial fertilizers, Ind. 302.

effect on water content of leaves, 763.

in soils, availability, effect of lime, Del. 157.

requirements and effects on citrus, Fla. 43.

Potassic fertilizers, blast furnace processes for production, U.S.D.A. 452.

Potassium—

carriers for tobacco and cotton, Ga.

Coastal Plain 38.

deficiency in rats, symptomatology and pathology, 885.

effect on photosynthesis in buckwheat, 168.

exchangeable, in Maryland soils, 24.

in citrus leaves and fruits, 633.

in semen, blood serum, and secretions of sexual glands, 323.

permanganate for stimulating callus and root development in grape cuttings, 46.

Potato—

bacterial soft rot, Fla. 54.

bacterial wilt and rot, 349, 798.

beetle, Colorado, natural enemies, 822.

beetle, three-lined, control, Wis. 506.

blight, late, relation to rainfall, S.C. 350.

blight, late, studies, Conn.[New Haven] 636; S.C. 54; U.S.D.A. 636.

disease known as "hay wire," Nebr. 637.

disease, undescribed, in West Virginia, 198.

diseases, control, Fla. 53, 54.

diseases in Florida, U.S.D.A. 343, 704.

diseases in Nebraska, 59.

diseases, survey in Oklahoma, U.S.D.A. 794.

diseases, virus, control, Iowa 199; Wash. 344.

diseases, virus, report, 500.

flakes, feeding value for work horses, 86.

flea beetle—

attack, varietal variations, Ohio 658.

Potato—Continued.

- flea beetle—continued.
 control, Va.Truck 371.
 on tobacco, control, Conn.[New Haven] 361.
 on tomato plants, control, 668.
 studies, Nebr. 657.
 insects, survey, Iowa 215.
 leaf spot in Oregon, U.S.D.A. 53.
 leafhopper—
 biology, injury, and control, 662.
 control, N.Mex. 215.
 control, effect on yield of peanuts, 507.
 control on dahlias, Conn.[New Haven] 813.
 effect of different copper-lime ratios, Ohio 658.
 resistance of varieties of apples to, Va. 816.
 white coating on foliage as repellent for, 513.
 leaves, carbohydrates in, effect of chloride ion, 185.
 mosaic, latent, resistance to, 500.
 plants, recovery after severe frost, Ohio 615.
 psyllid, control, N.Mex. 215.
 psyllid, culture methods for, 358.
 psyllid, studies, Nebr. 657.
 psyllid yellows, effect on seed stock from infected plants, 642.
 psyllid yellows in Wyoming, Wyo. 662.
 purple top disease linked with hair-sprout tubers, 642.
 purple top, spraying for, 55; Wyo. 55.
Rhizoctonia disease, S.C. 54.
 scab, control, N.J. 493; Wis. 493.
 scab resistance, studies, 350.
Sclerotinia rot, description, 350.
 soils in Connecticut, Conn.[New Haven] 587.
 stem wilt, Wyo. 55.
 storage, effect of bin treatments, Wyo. 55.
 tuber treatment, effect on stem infection with *Rhizoctonia solani*, 798.
 tubers, acidity of macerated tissue, 28.
 tubers, effect of light on solanine synthesis, 314.
 tubers, redox potential of macerated tissue, 28.
 tubers, redox potential of macerated tissue with degeneration diseases, 28.
 virus X, inoculation into chickens, production of antisera, 56.
 wilt disease, control by formaldehyde dust, 799.

Potatoes—

- as poultry food, 681.
 blackening during cooking, cause, Wis. 474.
 blooming, effect of pyrethrum dust, 599.
 breeding, Iowa 180; Wash. 325; Wis. 474.
 breeding for *Phytophthora* resistance, 350.

Potatoes—Continued.

 - of Portland, Oregon, ultraviolet component, 890.
- Superphosphate, triple, with dry and wetted limestone and dolomite, effects, 166.
- Superphosphates, effect on conservation of nitrogen in cow manure, Vt. 754.

Surra—

- experimental treatment in native horses in Philippines, 702.
- in bovines, curative treatment, 101.
- treatment with simultaneous subocculpit and intravenous injections of Bayer 205, 401.

Swede virus disease, dangerous, 57.

Swedes—

- boron requirements, Me. 43.
- for silage, yields, Wis. 474.
- Michigan's tablestock, marketing, Mich. 415.

Sweet corn—*see also* Corn.

- bacterial wilt, U.S.D.A. 493, 636.
- bacterial wilt resistance of inbred strains and crosses, 204.
- breeding, Iowa 186; Tenn. 333.
- fertilization, Ill. 334.
- growers' contracts for, Ill. 867.
- heredity in, Conn.[New Haven] 624.
- hybrid, new, N.Y.State 188.
- hybrid varieties, development, Conn. [New Haven] 624.
- hybrids and varieties, cut-off yields, Md. 625.
- hybrids, breeding and testing, Ill. 334.
- hybrids, tests, Wash. 333.
- inbred and hybrid lines, nature of drought resistance, Iowa 186.
- inbred and pure lines, quality, Ind. 332.
- inbred strains, breeding, Pa. 44.
- methods of applying fertilizers, Ohio 625.
- new strains, breeding and testing, Fla. 43.
- planting, rate and method, Ill. 334.
- polysaccharides in, Md. 624.
- resistant to earworm, new, 188.
- seed treatment with Semesan, Wyo. 55.
- smut in New York, U.S.D.A. 636.
- varieties, Mass. 782.
- varieties and strains, 626.
- varieties, cut-off data, 627.
- variety tests, 188; Idaho 770; Pa. 44.
- wilt and smut, notes, N.J. 493.
- yellow strains, relation to quality of canned product, 46.
- yield complex, Ill. 626.

Sweet pea flower buds, abscission, 50.

Sweet peas—

- fasciation in, Ohio 637.
- varieties, N.Mex. 186.
- varieties, bud drop in, Md. 625.

Sweetclover—

- alfalfa, and Sudan grass pasture, comparison, S.Dak. 91.
- and Albit wheat forage ensiled and cured as hay, 673.
- and Albit wheat mixtures as hay and silage crop, value, Wash. 375.
- and alfalfa, competition between, Wash. 325.
- biennial, eradication, Iowa 180.
- culture experiments, Okla. 39.
- Evergreen, new late-blooming, merits for pasture, Ohio 615.

Sweetclover—Continued.

- for swine, Pa. 79.
- hay, first- and second-year, nutritive value, Wash. 375.
- hay, toxicity, Wis. 538.
- nonbitter, development, Wis. 474.
- pasture, carrying capacity for lambs and ewes, Wyo. 80.
- pollinating agents, S.Dak. 67.
- seed production, effect of bees, S.Dak. 67.
- soil improvement from, effect of fall cutting, Ill. 302.
- value as soil-building crop, Iowa 157.
- variety tests, Iowa 180; Nebr. 614; Wash. 325.
- white, tetraploid and aneuploid, effect of heat treatment, 31.
- white, winter hardiness in, cytology and physiology, Iowa 180.

Sweetpotato—

- diseases, notes, N.J. 493.
- pulp, dried, feeding experiments, La. 236.
- seed stock, disease-free, propagation, Iowa 200.
- sprouts and slips, chemical treatments, Del. 199.
- storages, N.J. 540.
- weevil, control, U.S.D.A. 76.

Sweetpotatoes—

- acreage, yield per acre, and production, 1868-1923, U.S.D.A. 719.
- breeding, Iowa 180; Okla. 38; Tenn. 325.
- chopped, feeding experiments, La. 236.
- cooperative marketing, Tenn. 536.
- culture experiments, N.Mex. 181.
- fertilizer and green manure tests, Iowa 180.
- fertilizer experiments, Conn.[New Haven] 614; Ga.Coastal Plain 38; La. 181.
- for dairy feed, spacing and cost of production, La. 181.
- mutations in Porto Rico variety, 175.
- Porto Rico variety, vitamin C in, 730.
- production in Louisiana, La. 478.
- propagation tests, Iowa 180.
- slip seedling to avoid disease, Conn.[New Haven] 636.
- storage, Ind. 403.
- storage quality, factors affecting, Iowa 180.
- summary of studies, La. 624.
- variety tests, Iowa 180; La. 181; Okla. 38; P.R.Col. 771; Tenn. 325.
- vitamin G in, Tenn. 418.

Swine—*see also* Pigs and Sows.

- breeding stock, evaluation, Iowa 227.
- Danish Landrace breed, value for American conditions, Iowa 227.
- diseases of joints, 701.
- endometrium, production and changes in, 320.
- erysipelas, Ill. 544.
- improvement, regional research laboratory for, editorial, 2.
- influenza, 391.

Swine—Continued.

- inverted nipples in, inheritance, Idaho 528.
- maintenance metabolism, 230.
- measurements, methods for obtaining, 672.
- nodular worm, survival of eggs and infective larvae, 244.
- plague, 545.
- plague, immunization by formalized vaccine, 544.
- pox in Iowa, 107.
- production, inbreeding v. outcrossing, Okla. 78.
- reproduction, effect of protein intake, Okla. 78.

Sylvatic plague committee, 103.

Symptomatic anthrax, *see* Blackleg.

Swainsonella—

acron, notes, 659.

pictipes, *see* Peach borer, lesser.

Syndactyl in swine and results on inheritance of color, 177.

Systera frontalis on cranberry, Mass. 815.

Tabanidae of Delaware, biology and control, Del. 215.

Tabanus genus, variations of seasonal cycle in, 515.

Tachypterus quadrigibbus, *see* Apple curculio.

Tacnia *aginata*—

egg production in, 521.

eggs, ridding pastures of, 101.

growth and propagation, 657.

on sewage farms, economic waste caused by, prevention, 696.

Tania spp. in dogs, 253.

Tarniothrips—

pini, notes, 661.

simplex, *see* *Gladiolus* thrips.

Tangalos, ascorbic acid in, 730.

Tangerine, ascorbic acid in, 730.

Tankage—

as protein supplement for steers, Ill. 374.

dry-rendered reduction and packing plant, for pigs, Ohio 674.

effect on flavor of milk, S.Dak. 91.

materials as protein supplements for pigs, Ohio 674.

soybean oil meal, and roasted soybeans, relative value for pigs, Ind. 374.

supplemental value with hegarl proteins, 377.

Tannin from hemlock bark, economic possibilities, U.S.D.A. 443.

Tapeworms—

in dogs, 253.

in sheep and rabbits, Wyo. 67.

Taphrina corulescens, notes, U.S.D.A. 794.

Tariff, British, partial compensation for, U.S.D.A. 265.

Tarnished plant bug—

on alfalfa during drought, Wis. 506.

reduction in alfalfa seed production by, Utah 67.

studies, Ind. 360.

Taros, variety tests, P.R.Col. 771.

Tarsonemus—

bancrofti, new pest of sugarcane in continental United States, 812.

latus, *see* Broad mite.

mites, contamination of bacterial cultures by, 815.

Tax delinquency—

and soil erosion, correlation, U.S.D.A. 118.

farm, N.J. 551.

rural, in Pennsylvania, 118; Pa. 142.

Taxation, farm, graphic summary, U.S.D.A. 267.

Taxes—

and tax delinquency on farms, Ill. 410.

delinquent, amount per acre on farm real estate, S.C. 117.

direct and income, studies, S.C. 117.

motor vehicle property, assessment and collection in Maryland, Md. 267.

paid by farmers and city residents in proportion to income, Wis. 351.

processing, by whom paid, 873.

retail sales, problems of collection, Md. 267.

Taxonomy, experimental, 166.

Tea plant growth and photoperiodism, 168.

Teak timber, damage by beehole borer, 216.

Teara contraria infesting myall foliage, injury to sheep, 853.

Teeth—

decay, relation to capillary resistance, Utah 140.

defects, relation to fluorine of water in Foochow, 728.

effect of low fluorine intake, 276.

mottled, relation to fluorine in drinking water in England, 728.

primary, effect of nutrition, 890.

structure, relation to bacterial toxins and vitamin C, 572.

Telephones, number of, Me. 116.

Tellurium—

and selenium, comparison of effects on plants and animals, 796.

selenium, arsenic, and vanadium, minimum fatal doses, comparison, 100.

Temperature—*see also* Climate and Soil temperature.

constant, apparatus for, 764.

dangerously low winter, species response to, Ohio 634.

effect on responses of plants to photoperiod, 27.

Tenebrio molitor, *see* Mealworm, yellow.

Tenebroides nana, notes, Hawaii 90.

Tennessee Station, report, 431.

Tent caterpillar—

eastern, decrease of, Conn.[New Haven] 813.

eastern, parasite of, biology, 518.

eastern, studies, 659.

forest, lime-sulfur for control, 812.

forest, notes, 659; Conn.[New Haven] 813; Mont. 66.

forest, parasite of, biology, 518.

in orchards, control, Conn.[New Haven] 813.

- Tephrosia*—
as insecticide, review of literature, U.S.D.A. 215.
toxicaria samples, chemical and insecticidal tests, 812.
- Termites—
and termite damage in Trinidad, 511.
control, 71; Conn.[New Haven] 813; Ill. 360.
in New Jersey, 363.
new species in Philippines, 661.
studies, Conn.[New Haven] 657.
- Terrace cross sections, factors affecting, 110.
- Terraces, soil-saving, N.J. 549.
- Terracing with power equipment, cost, 162.
- Testicular heterotransplantation in rats and mice, 471.
- Testis, embryonic and postnatal development in guinea pigs, 320.
- Testis, undescended, hormone production in, 323.
- Testosterone and related compounds, progesterone-like action, 470.
- Tetanus in animals, alum-toxoid as vaccine for prevention, 698.
- Tetany—
factors causing, Wis. 562.
with hypomagnesemia in a dairy cow, 103.
- Tetrameres*—
crani. morphological and biological studies, 244.
helix, notes, 656.
- Tetramorium caespitum*, see Ant, pavement.
- Tetranychus*—
ibocedri on incense cedar, 521.
telarius, see Red spider.
- Tetraploidy in barley, heat induced, 766.
- Tetrastichus haitiensis*, notes, P.R.Col. 226.
- Tetraploium abietis*, notes, U.S.D.A. 224.
- Texas Station, abstracts of bulletins and circulars and contributions by staff members, 894.
- Textile plants, diseases and pests, 55.
- Textiles, household, use by farm families, S.C. 140.
- Thallium—
molt in sheep, 398.
sulfate, effect on soils, Calif. 310.
sulfate for ant control, Ill. 360.
toxicity and tobacco frencing, 206.
- Theelin prepared from stallion urine, human urine, and from theolol, comparison, 769.
- Thellieria dispar*, development in bovine and in tick *Hyalomma mauritanicum*, 105.
- Thermobia domestica*, see Firebrat.
- Thielavia* root rot of tobacco, Conn.[New Haven] 351.
- Thiobacillus* spp., sulfide production by, 149, 603.
- Thistles, Canada—
and whitetop, control, Wyo. 40.
control equipment, Ind. 408.
test of chemicals for, Ill. 324.
- Thistles, Russian—
calcium and phosphorus content, Wyo. 80.
- Thistles, Russian—Continued.
digestible nutrients and metabolizable energy, 678.
- Thorny-headed worm in whitethroated sparrow, N.J. 546.
- Thrips—
control by nicotine, effect of spreaders, 512.
Florida, notes, Fla. 65.
on seedling cotton, S.C. 67.
relation to set of strawberries, Ill. 350.
tabaci, see Onion thrips.
- Throscoryssa citri*, notes, 372.
- Thrushes and mimids of New Jersey, N.J. 212.
- Thyanta custator*, unusual abundance in South Dakota, 65.
- Thylogdrias contractus* in Texas, 359.
- Thymus, effect on relation of growth to mineral metabolism, Fla. 128.
- Thyroid—
and parathyroid in birds, antagonism, 681.
bovine, iodine in, Ohio 687.
- Thyrostroma compactum*—
cultural characters from Chinese elm, 196.
on *Ulmus pumila*, 63.
- Thyroxine, effect on lactation in hypophysectomized guinea pigs, 321.
- Thysanoptera—
from American conifers, 661.
of Formosa, 661.
western, distribution and hosts, 661.
- Tick fever, see Piroplasmosis.
- Tick population in western Montana, seasonal prevalence, 671.
- Ticks—
attachment to lambs, bacterial infection as sequel, 544.
dipping lambs for control, Wyo. 81.
of United States, relation to disease in man, 68.
- Tillage—
and traction research problems, fundamental approach, 110.
experiments and crop rotations. U.S.D.A. 773.
tools, load studies, 408.
tools, tests, 408.
- Tilletia tritici*—see also host plants.
sexuality and development in, 797.
- Timber—see also Wood.
growth fluctuations, effect of climate, 341.
harvesting and marketing in New York, 52, 791.
market, international, organization, 264.
- Timbers, house, injured by anobid beetles, Conn.[New Haven] 813.
- Timothy—
and alfalfa, alfalfa, and alfalfa-orchard grass mixtures, comparative yields and duration, Ohio 615.
and alfalfa meadow as summer and fall pasture, merits, Ohio 615.
fertilizer experiments, R.I. 771.

Timothy—Continued.

- hay, producing, baling, and loading for market, U.S.D.A. 474.
- improving protein content by nitrogen fertilizers, 780.
- protein in, increasing by nitrogen fertilization at heading, N.J. 473.
- variety tests, Ky. 771.

Tinea pellionella, see Clothes moth, case-bearing.

Tincola bisaciliella, see Clothes moth, webbing.

Tingitidae, new Indian, 216.

Tipulidae, West Indian, new or little-known species, P.R.Col. 222.

Tires—

- pneumatic, for horse drawn vehicles, 259.
- pneumatic, for tractors in English farming, 259.
- rubber, performance on tractors, Nebr. 706.
- rubber, tests on farm tractors, Mont. 710.

Tissue respiration, new method for study, 9.

Toad flax, yellow, control, Idaho 771.

Toad, giant—

- introduction into Queensland, 106.
- Surinam, development, P.R.Col. 212.
- Surinam, food habits, P.R.Col. 212.

Toad, imported, status, P.R.Col. 814.

Toads, parasites in North Carolina, 337.

Tobacco—

- bacterial diseases in Canada, U.S.D.A. 794.
- bacterial leaf spots, overwintering, Ky. 794.
- beds, effect of burning to control white grubs, Ky. 814.
- black root rot, Mass. 794.
- black shank disease, Ky. 794; U.S.D.A. 636.
- blackfire disease, Wis. 493.
- breeding, Pa. 39.
- Broadleaf, fertilizer experiments, Conn. [New Haven] 331.
- brown root rot, hypothesis of, 643.
- budworm, seasonal availability of food plants, 73.
- cigar leaf, culture, Conn. [New Haven] 330.
- cigar-wrapper strains resistant to black shank, Fla. 54.
- cropping systems, comparison, Mass. 771.
- crown gall and spontaneous tumors of hybrids, 197.
- cryolite as insecticide for, Tenn. 360.
- culture experiments, Ga.Coastal Plain 38.
- curly top virus, movement and translocation of food, correlation, 500.
- diseases, Conn. [New Haven] 351.
- diseases in Canada, U.S.D.A. 343.
- diseases, studies, Fla. 54; Ga.Coastal Plain 59.
- downy mildew (blue mold)—
- and bacterial leaf spots in Kentucky, U.S.D.A. 492.
- developments, 199; U.S.D.A. 492.

Tobacco—Continued.

downy mildew (blue mold)—contd.

- distribution and severity, relation to January temperatures, U.S.D.A. 794.
- early appearance in Georgia, U.S.D.A. 53.
- first appearance in various States, U.S.D.A. 53.
- studies, Ky. 794; S.C. 54; U.S.D.A. 343, 493, 636, 794.
- effect of preceding crops, Mass. 771.
- effect of soil nitrogen content, Ky. 771.
- farms, management, P.R.Col. 262.
- fertilizer experiments, Conn. [New Haven] 614; Ga.Coastal Plain 38; Ky. 771; Pa. 39; P.R.Col. 771.
- fla beetle, control, Conn. [New Haven] 657; Ky. 814.
- fla beetle, relative toxicity of insecticides, S.C. 67.
- frenching and thallium toxicity, 206.
- growth, effect of iodine, Ky. 757.
- harvesting at different stages of maturity, Conn. [New Haven] 614.
- Havana seed, control of potato fls beetle on, Conn. [New Haven] 361.
- Havana seed, time of harvesting, Conn. [New Haven] 330.
- hornworms, insecticides used in field tests, U.S.D.A. 216.
- hybrids, tumors in, 800.
- insects, abundance, Conn. [New Haven] 362.
- irrigation experiments, Conn. [New Haven] 330, 614.
- leaf, anatomy, Conn. [New Haven] 331.
- marketing through northern Wisconsin cooperative pool, decline in, Wis. 351.
- mildew, control in hotbeds, Ga.Coastal Plain 60.
- mildew, control in tobacco plant beds, 196.
- mosaic disease, action of proteoclastic enzymes on virus fraction, Mo. 643.
- mosaic disease in solanaceous plants, hereditary factors, 197.
- mosaic disease of peppers, inheritance of resistance, 499.
- mosaic, effect of weather, Wis. 493.
- mosaic, epiphytology, relation to contaminated soil, 197.
- mosaic, notes, 352; Ky. 794; P.R.Col. 795.
- mosaic virus—
- activity, relation to pH values, 60.
- crystalline preparation, improved method, 800.
- inactivation by ascorbic acid, 197.
- inactivation by ultraviolet light, 351.
- proteins, crystalline, studies, 205, 643.
- representative strains, 351.
- Stanley's crystalline, and intracellular inclusions, 196.
- strains, comparative properties of proteins, 197.

Tobacco—Continued.

- moth, biology and control in closed storage, U.S.D.A. 664.
- plant bed diseases in Florida and Kentucky, U.S.D.A. 636.
- plant bed fertilization, Fla. 38.
- plant bed insects, control, Ky. 508.
- plant bed management studies, Ga. Coastal Plain 38.
- plant, chemistry of, Conn.[New Haven] 580.
- potassium content, determination, Pa. 39.
- prices, trends and variations between markets, Ky. 866.
- root rot resistant varieties, Ky. 794.
- rotations, Ohio 615; Pa. 39.
- seedbed survey in Wisconsin, U.S.D.A. 636.
- seedlings, *Peronospora tabacina* in, infection and sporulation, 197.
- seeds, germination after 4 years in different types of storage, Fla. 38.
- seeds, producing methods in field, Fla. 38.
- spacing tests, Mass. 771.
- stalk diseases, new, Ky. 794.
- stalks, hemicelluloses of, Mass. 739.
- statistics, annual report, U.S.D.A. 719.
- studies, S.C. 39.
- variety tests, Ga.Coastal Plain 38; Pa. 39; P.R.Col. 771.
- virus proteins, Stanley's intracellular crystallization, 793.
- wildfire, Pa. 54.
- worm, notes, Conn.[New Haven] 362.
- yellow strain, systemic development, effect of nutrition, 198.

Tomato—

- bacterial canker control, seed extraction method for, Utah 54.
- blight, late, studies, Conn.[New Haven] 636.
- blossoms, structure, Ohio 625.
- blossom-end rot, development, 197.
- blossom-end rot, relation to nutrient salt concentration, 501.
- curly top in Utah, U.S.D.A. 636.
- curly top, losses from, Utah 54.
- curly top susceptibility, effect of shade, Utah 54.
- diseases causing severe damage, Wis. 493.
- diseases, control, Fla. 54.
- diseases, greenhouse, control, Mass. 794.
- diseases, notes, N.J. 493.
- diseases, virus, 501; Ind. 343.
- foot rot control, Del. 199.
- fruitworm, control operations, timing, Utah 67.
- Fusarium* wilt, Tenn. 343.
- Fusarium* wilt resistant varieties, breeding for greenhouse and canning industries, Ohio 637.
- galls, effect of enzymes and amino acids, 201.
- leaf mold resistant variety, progress in development, Ohio 637.

Tomato—Continued.

- leaf spot control, Tenn. 343.
 - leaf spot-resistant varieties, development, Tenn. 333.
 - mosaic virus, effect of commercial fertilizers, Ind. 343.
 - Phoma* rot, control, Fla. 502.
 - pinworm, studies, Pa. 67, 73.
 - plant, growth and metabolism, 27.
 - plant sap, electrical conductivity, effect of soil moisture and fertilizers, 601.
 - plants, correct handling, [N.Y.]Cornell 189.
 - plants grown with limited nitrogen, effects of carbon arc light, 627.
 - plants, locally grown, value, N.Y.State 784.
 - pockets or puffs, effect of environment, 197.
 - root tips, excised, growth rates, seasonal fluctuations, 600.
 - seed, pathogenic associates, 501.
 - seed, production, Ind. 332.
 - seed treatment, 644.
 - streak disease caused by virus of potato X group, 56.
 - streak virus, strain, causing, 206.
 - tissues, healthy curly top and bean-tomato, differences, Utah 54.
 - transplants, effect of seedbed treatments, Ohio 637.
 - transplants, effect of spray materials, Ohio 502.
 - virus diseases, Fla. 54.
 - virus, ring-spot type, 197.
 - vitamin C in, Fla. 123.
 - wilt, control, Fla. 54.
 - wilt disease due to *Bacillus solanacearum*, P.R.Col., 795.
 - wilt disease, new, N.Y.State 207.
 - wilt, *Fusarium* v. *Verticillium* responsible for crop failure, Utah 54.
 - wilt resistant variety, Riverside, 803.
 - worm, notes, Conn.[New Haven] 362.
- Tomatoes—
- adapted to Wisconsin, Wis. 460.
 - and tomato juice as antiscorbutics, Mass 879.
 - ascorbic acid content, effect of home canning and storage, 573.
 - breeding, N.J. 480; S.Dak. 44; Wash. 333.
 - canning varieties, Ill. 334.
 - carbon dioxide assimilation by, R.I. 783.
 - color, effect of temperature, Md. 624.
 - cost of production, U.S.D.A. 121.
 - costs and practices with, Ind. 410.
 - crossing over in, 317.
 - culture and breeding, Fla. 43.
 - culture experiments, Ga. 43; La. 186.
 - culture in greenhouse, Okla. 44.
 - effect of boron deficiency, 480.
 - effect of supplemental illumination, Ohio 625.
 - fertilizer experiments, Ga. 43; La. 186.
 - fertilizer requirements, P.R.Col. 783.
 - frost protection for, Fla. 12.
 - fruit setting, factors in, 482.

Tomatoes—Continued.

- greenhouse, fertilizers for, Ill. 334.
- greenhouse, potential pest, 515.
- greenhouse, spray program for, 644.
- growth, effect of iodine, Ky. 757.
- growth, need of minor elements for, 482.
- growth, relation to nutrient salt concentration, 501.
- growth, relation of sodium to calcium in, N.J., 450.
- haploid Marglobe, short cut for making pure lines, 767.
- in poor soil, need of minor elements for, 784.
- in sand cultures, copper requirements, 450.
- inheritance in, Iowa 180.
- loam v. sandy types of soil for, R.I. 783.
- mineral salts and vitamins in, factors affecting, Ohio 625.
- new, breeding, Ill. 334.
- Penn State, improvement, Pa. 44.
- photosynthetic efficiency, effect of light intensity, 458.
- puffing in, factors affecting, Tex. 627.
- quality, effect of storage, 784.
- quality, relation to nutrition and healthy foliage, Ind. 332.
- ripening, effect of copper sprays on, 197.
- Riverside, variety resistant to two wilt diseases, 803.
- seedlessness in, 627.
- shipping qualities, effect of fertilizers, Okla. 44.
- spray injury, R.I. 795.
- spraying, effects, 60.
- summary of studies, La. 624.
- training, Mass. 782.
- varieties, Iowa 186; Mass. 782.
- varieties, temperature requirements, N.J. 480.
- varieties, type and severity of fruit cracking in, 784.
- variety tests, Ga. 43; La. 156; Ohio 625; Pa. 44; R.I. 753; S.C. 44.
- yield, relation to lime and organic matter, N.J. 480.

Tonsils, human, vitamin C in, 426.

Tortrix postvitana, overwintering in apple orchards, 821.

Turulin, crystalline, and international vitamin B₂ standard, 279.

Township organization in Missouri, 413.

Toxoplasma paddae in North American birds and attempted transmission to canaries and chickens, 860.

Tortroptera—

aurantiae, see Citrus aphid, black.

graminum, see Green bug.

Tracheobronchitis, infectious, of horses, 401.

Traction mechanisms of track-laying type, use of rubber in, 111.

Tractor—

and horse power, costs, Ill. 410.

lubrication, Ill. 403.

tire size, effect on drawbar pull and travel reduction, 407.

Tractor—Continued.

trailers, dual-wheeled, Wis. 549.

work, cost of, 405.

Tractors—

and cost of tractor power on grain farms, U.S.D.A. 405.

farm, pneumatic equipment for, 239.

field machinery hitches for, S.Dak. 109

on central-Maine potato farms, Me. 116.

rubber tires v. steel wheels for, Ind. 403; Mont. 710.

stop hitches for, Pa. 109.

Trade, foreign—

significance to Wisconsin farmers, Wis. 551.

structural changes in, effect on Corn Belt agriculture, Iowa 260.

Tradescantia reflexa, direction of colling in, 84.

Traffic accidents, relation to night blindness, 886.

Transdehydroandrosterone, assay and effects on gonadectomized rats, 470.

Transpiration—

of apple leaves, effect of water deficiency, 47.

of plants, continuous measurement, 457.

rate, relation to rate of absorption of water in plants, 598.

Tree —

cankers in Iowa, fungi associated with, 637.

diseases in Massachusetts, U.S.D.A. 53.

diseases in New Jersey, U.S.D.A. 794.

seedlings, effect of fertilizing, Conn. [New Haven] 587.

wound dressings, Ohio 483.

Trees—

borer enemies, control, Mo. 74.

coniferous, see Conifers.

decay studies, cultural identification necessary, 197.

delayed leaf-fall in, effect of street lights, 762.

diameter measurement, modified steel tape and tree-fork for, 791.

evergreen, see Evergreens.

experimental, labels for marking, U.S.D.A. 216.

forest, effects of autumn 1935 cold wave in northern Idaho, U.S.D.A. 53.

forest, spacing in plantings, Pa. 50.

forest, tests, Fla. 43.

growth rate in Arkansas, soil factor affecting, 51.

harvesting and marketing in New York, 52.

injection of fertilizer solutions, 172.

injury by deer in Oregon, protection, 653.

New England forest, effect of root development on height and diameter growth, Vt. 789.

ornamental, diseases of Virginia, U.S. D.A. 493.

our friends, treatise, 50.

physiology, yearly cycle in, 761.

Trees—Continued.

- producing, establishment and maintenance of nurseries for, Iowa 195.
- protection from rabbits, U.S.D.A. 190.
- sap ascent in, 456.
- shade, determining nutrient needs, 195.
- shade, insects affecting, control, 67.
- shelterbelt—see also Shelterbelt tests, Fla. 43.
- summer wood production in, 450.
- Texas root rot of, N.Mex. 200.
- volume, growth, and yield studies, Iowa 195.

Trematodes—

- parasitic in birds and mammals, life histories, 809.
 - potential longevity, 213.
- Treponema podorici*, notes, 854.
- Triaspis curculionis*, parasite of apple curculio, N.Y.State 75.

Tribolium—

- castaneum*, notes, Hawaii 99.
 - confusum*, see Flour beetle, confused.
- Triccephalobus longicaudatus*, notes, 808.

Trichina—

- cysts, calcification in cats, effect of irradiated ergosterol and irradiated milk, 245.
 - infection in rats, relation to diet, 849.
- Trichinella spiralis*—
- human infections with, 246.
 - localization in muscle of host, 851.
 - notes, 656.
 - of rats, effect of irradiated ergosterol, 245.

Trichinosis—

- studies, 244.
 - toxic factor in, 244.
- Trichiocampus ciminatus*, notes, Conn.[New Haven] 813.

Trichocephalis serratus from ocelot, 656.*Trichoderma lignorum*—

- antagonistic action on *Actinomyces scabies* and *Rhizoctonia solani*, 795.
- toxic substance, isolation from culture filtrate, 55.

Trichogramma minutum—

- mass production, 670.
- notes, 365.
- parasite of cranberry fruitworm, Mass. 815.

Trichomes as centers for local virus infections, incidental importance, 494.

Trichomonas—

- columbae*, fatal to the hawk, 245.
- disease of cattle, 544.
- foetus cultivation free from bacteria, 245.

Trichomoniasis in cattle, 244, 398.

Trichoptera of Minnesota—

- biology, 664.
- immature stages, 515.

Trichostrongylus—

- axei*, notes, 701.
- in man, record for, 213.
- instabilis*, notes, 544.

Trichuris—

- ovis* in alimentary tracts of goats, 399.
- vulpis* in dogs, 252.

Trifidaphis phacellii, notes, S.C. 67.

Triploidy in corn, origin, 175.

Trisodium phosphate for cleaning dairy equipment, 242.

Triticum monococcum and *T. aegeolopoides*, cytogenetic studies, Mo. 316.*Tritogenaphis ambrosiae*, control, 511.

Truck crop farms with greenhouses, Rochester area, [N.Y.]Cornell 867.

Truck crops—

- fertilization, Ill. 334; Pa. 44; R.I. 783.
- of Florida, inter-State and foreign competition, Fla. 121.
- soil pH needs, Fla. 43.
- variety tests, Fla. 43.

Typanosoma—

- equiperdum*, notes, 852.
- vivax*, parasite of livestock in Mauritius, 248.

Tryptophane, role in chick nutrition, N.J. 527.

Tsetse-flies, food hosts, 519.

Tubercle bacilli—

- avian, in lymph nodes of cattle, 398.
- pathogenicity of strains for rabbit when inoculated into anterior chamber of the eye, 849.

Tuberculin—

- avian, test in ducks, 255.
- intradermic reaction in cattle, histologic features, 102.
- reactors, bovine skin-lesion problem, 540.
- tolerance, effect of crystalline vitamin C, 281.

Tuberculosis—

- bacteria, bovine and human types, rapid growth on blackened potatoes, Wis. 538.
- control, Ostertag method, 544.
- effect on development of *Brucella abortus* infection, 392.
- eradication, papers on, 107.
- human, in cattle, 544.
- in cattle, control work in Denmark, 544.
- in fur-bearing animals, 848.
- in poultry, prophylaxis, and B. C. G experiments, 703.
- skin, of cattle, 700.
- studies, 397.
- surgical cases and vitamin C therapy, 731.

Tularemia in man, sources of infection and seasonal incidence, 397.

Tulip sunscald, 807.

Tulips—

- cytogenetic studies, Md. 624.
- varieties, N.Mex. 186.

Tumors—

- formation in mice, relation to gene T for brachyury, genetics, 468.
- in mice, comparison of high tumor lines, 768.
- in mice, Z stock \times I stock, 768.

Tumors—Continued.

of tobacco hybrids, 500.
parasitic, in wild birds, 706.

Tung oil—

production test, La. 196.
summary of studies, La. 624.
tree diseases in Louisiana, La. 64.
tree foliage, normal, diseased, and zinc-treated, comparative zinc content, Fla. 53.

trees, propagation, breeding, and fertilizing tests, Fla. 43.

trees, varieties, P.R.Col. 783.

Turf disease control, R.I. 795.

Turf, establishing and maintaining, N.J. 473.

Turkey—

disease, recent outbreak in Virginia, 549.
eggs, chemistry of, 686.

eggs, hatchability, S.Dak. 79.

embryo, development, relation to humidity, 682.

flocks, differences in, testing, Nebr. 674.

Turkeys—

and chickens, protein requirements, comparison, Idaho 826.

artificial lights for, Iowa 228.

blood disease of, 549.

breastbone deformity in, relation to shape of roosts, Wyo. 60.

breeding season, experimental modification, 324, 531.

Bronze, dressing shrinkages, 531.

Bronze, egg production, 89.

buying for household, quality demands in, Vt. 893.

caponizing, Iowa 228.

chromosomes in, morphology, 464.

crop worms in, macroscopic differentiation of species, 706.

dried grasshoppers for, value, Okla. 78.

ducks, geese, and pheasants, comparative growth rates, 686.

effects of additions of iron to standard ration, Nebr. 674.

feeding costs, Utah 80.

incubation studies, Ky. 827.

Narragansett, egg size in relation to growth, 89.

nutrition, Pa. 79.

production, W.Va. 382.

pullorum disease in, Mass. 856.

raising, peanuts and peanut products for, Fla. 78.

wild, on Missouri Ozark range, U.S.D.A. 652.

Turnip—

aphid, notes, 801.

brown heart, 644.

greens grown on iron-deficient soils, iron in, Fla. 128.

virus disease, dangerous, 57.

Turnips—

cost of production, U.S.D.A. 261.

effect of boron deficiency, 480.

floral primordia differentiation, 334.

in sand cultures, copper requirements, 480.

role in meat production in Britain, 673.

Twinning—

in cattle, new results of studies, 35.
monozygotic in a ewe, 471.

Tylenchohynchus claytoni n.sp., description, 808.

Tylenchus dipsaci, disease due to, Okla. 58.

Tympanis canker of red pine, 650.

Typhaea stercorea, notes, Hawaii 99.

Typhlocyba pomaria, see Apple leafhopper, white.

Typhoid, avian—

breeding for resistance to, Iowa 253.

eradication from flocks, 705.

naturally infected field cases, N.C. 548.

Typhoidlike diseases in laboratory animals,

resistance and susceptibility to, Iowa 253.

Typhula graminis on turf, N.J. 493.

Tyroglyphus—

dimidiatus, notes, 814.

longior var. *oastellani*, notes, 815.

mites, contamination of bacterial cultures by, 815.

siro, identity, 815.

Udder—

parenchyma, histological study, 698.

quarters, frequency of mastitis in, 248.

Udders—

pathological changes with mastitis, 700.

staphylococcal infections, 249, 852.

Ultracentrifuge, vacuum type driven by electricity, 764.

Ultraviolet—

irradiation of milk, vitamin D potency, relation to time, 238.

irradiation v. cod-liver oil as sources of vitamin D for confined laying hens, 528.

light, inactivation by tobacco mosaic virus, 351.

radiation for rearing of chickens, 651.

radiation in corn, genetic effects, 31.

radiation of plants, Pa. 26.

Umbrella fabrics, durability and resistance to water, 283.

Undulant fever—

diagnosis, 394.

treatment with Fouadin, 105.

United States Department of Agriculture—

appropriation act, 1938, editorial, 289.

Library, list of periodicals received in, 735.

list of publications, 1931-35, 141.

notes, 144.

technical bulletins Nos. 1-500, index, 431.

Upstream engineering and conservation of wildlife resources, U.S.D.A. 707.

Uranium, effect on tomatoes, 480.

Urinary—

antiseptics, 244.

calculi in sheep, Ind. 391.

calculi in sheep, formation, effect of calcium and phosphorus supplements in ration, Ind. 375.

calculi, studies, 244.

nitrogenous constituents excreted daily by children, effect of diet on constancy, 726.

Urine—

- ascorbic acid in, effect of administration of sodium bicarbonate and ammonium chloride, 282.
- ascorbic acid in, phosphotungstic acid method, 153.
- chemical and morphological examination, 244.
- chlorides in, microdetermination, 9.
- of lactating mothers, vitamin C in, effect of vitamin C administration, 280.
- pregnancy, effect on pituitaries of rats, 769.
- pregnancy, pregnandiol in, 613.
- stallion and human pregnancy, as sources of theelin, comparison, 769.
- variation in lethal effect on horse sclerostome larvae in manure, 245

Urocystis cepulae, parasitic relations to *Allium fistulosum*, 802.

Uromyces phascoli typica, notes, 199.

Ustilago—

- avenae*, sexual fusion under natural conditions, 345.
- crameri* chlamydo-spores, viability and longevity, 638.
- hordei*, seasonal cycle, 198.
- levis*, notes, 202.
- nigra*, pathogenic strains in, 202.

Utah Station, notes, 576.

Utah Station, report, 142.

Vaginitis, malignant diphtheretic, of cattle, 848.

Vanadium, arsenic, tellurium, and selenium, minimum fatal doses, comparison, 100.

Veal, grading and stamping under Government inspection, U.S.D.A. 81.

Vegetable—

- diseases in Nassau County, Long Island, U.S.D.A. 493.
- diseases in New York, U.S.D.A. 636.
- diseases on Chicago market, U.S.D.A. 203, 644.
- diseases, studies, N.J. 493; U.S.D.A. 794.
- diseases, treatise, 801.
- farming in New York, economic studies, [N.Y.]Cornell 867.
- farms, yields, costs, and net income, Ill. 410.
- gardening, *see* Gardening, vegetable.
- juices, unfermented, preparation, N.Y. State 783.
- leaf diseases, U.S.D.A. 343.
- oils, *see* Oils.
- seed, production, N.Mex. 186; P.R.Col. 783.
- seed treatments, Mass. 794; R.I. 783.
- tissues, ascorbic acid in, state of, 740.
- weevil, nomenclature, 372.

Vegetables—

- canned, strained, vitamin C in, Mich. 425.
- canned, strained, vitamins in, Mich. 421.
- carlot shipments and unloads, U.S.D.A. 123.

Vegetables—Continued.

- Charleston as market for, W.Va. 121.
 - culture, Alaska 782; Can. 625, 783.
 - culture at higher altitudes, Md. 625.
 - determination of quality by physiological methods, R.I. 783.
 - fate of constituents during cooking, Mass. 789.
 - fertilizer requirements, Fla. 43.
 - frozen-pack, markets for, Tenn. 875.
 - grades, price trends, and sales on Indianapolis Producers' Market, Ind. 717.
 - improvement, Mass. 782.
 - in storage, changes in, Md. 624.
 - interim report of Federal Trade Commission on, 874.
 - irrigation, Tenn. 333.
 - irrigation, value, Wyo. 44.
 - lime requirements, N.J. 480.
 - market diseases, U.S.D.A. 203.
 - marketing, [Conn.]Storrs 550.
 - marketing by motor truck in western Maryland, Md. 717.
 - marketing, changes in, N.J. 351.
 - metabolism, relation to preservation, 481.
 - new uses for, N.Y.State 189, 783.
 - nutritional requirements, Can. 625.
 - Philadelphia market for, Pa. 121.
 - preservation by freezing, Oreg. 724.
 - production for local consumption in Middle Rio Grande Conservancy District, N.Mex. 715.
 - soil reaction requirement, Conn.[New Haven] 624.
 - storing, precooling, and freezing, Ind. 332.
 - time of planting, Wyo. 45.
 - varieties, Alaska 782; Can. 625; N.J. 480.
 - variety tests, Fla. 43; Ga. 43; Okla. 44; S.C. 44; Wyo. 45.
 - vitamin C in, 151, 280.
 - vitamins in, effect of processing, Mass. 568.
 - water requirements, Ohio 625.
- Vegetation—*see also* Plants.
- aquatic, of Susquehanna and Delaware areas, 756.
- Vehicle speeds on Connecticut highways, U.S.D.A. 550.
- Vehicles, horse drawn, pneumatic equipment for, 259.
- Velvetbean caterpillar, serious pest of alfalfa, 365.
- Velvetbeans—
- fertilizer experiments, Ga.Coastal Plain 38.
 - interplanting of corn varieties with, Fla. 38.
 - variety tests, Ga.Coastal Plain 38.
- Ventilating, heating, and air conditioning, principles, treatise. 259.
- Vermont Station, notes, 288.
- Vermont University, notes, 288.

Verticillium—

albotruncum of vegetables new to Florida.
U.S.D.A. 794.

distribution on elm in Massachusetts
U.S.D.A. 53.

nictrostratosum, notes, 639.

rhizophagum on elm root, 210.

sp. causing decay in apples, 645.

spp. on *Buxus sempervirens*, U.S.D.A.
493.

wilt of eggplant, Ill. 343; Mass. 794.

wilt of peppermint, 197.

Vespidæ, control, Mont. 66.

Vetch—

and barley, costs involved in growing.
Alaska 770.

and oats, costs involved in growing,
Alaska 770.

bruchid in United States, 823.

culture experiments, Okla. 39.

fertilizer experiments, Okla. 39.

hairly, a temporary grazing crop, Ga.
Coastal Plain 78.

seed, toxic substances in, 340.

seed, untreated and disemibittered, feed-
ing to cows, effect, 839.

seed, untreated, feeding trials for milk-
ing cows, 840.

variety tests, Okla. 38.

Veterinary—see also Animal diseases.
medicine, treatise, 694.

Village, Utah, historical background, Utah
124.

Vineyards—see also Grapes.

development, Okla. 44.

Violets, effect of phosphorus on chromosome
and nuclear volume in, 607.

Vioosterol, see Ergosterol, irradiated.

Vireo, Latimer's, nesting activities, P.R.Col.
212.

Virginia—

creeper leafhopper, control, Mont. 66.

Polytechnic Institute, notes, 576.

Station, notes, 288, 897.

Truck Station, notes, 897.

Virus—

diseases, histology of necrotic lesions,
56.

mutation and gene concept, 317.

neutralized and antibody, liberation
from antiserum-virus precipitates, 201.

proteins, ultracentrifugal study, 638.
studies, 56, 501.

Viruses, animal, variation in, 109.

Viruses, filtrable, studies, 233.

Vitamin A—

activity of butterfat, 97.

activity of leafhopper-yellowed alfalfa,
640.

activity of palm oil, 279.

alfalfa leaf meal as source for chick-
527.

and carotene, utilization by rat, com-
parison, 569.

and dark adaptation, 886.

and glycuronic acid in mucine metabo-
lism, interrelation, 135.

Vitamin A—Continued.

antimony trichloride reaction for, spec-
trographic studies, 150.

carotene v. halibut-liver oil as source for
children, Ill. 419.

chemical structure, relation to spectro-
scopic absorption, 150.

concentrate, crystalline, 150.

concentrate, feeding, effect on reproduc-
tion in cattle, Mass. 839.

deficiency, effect on central nervous sys-
tem, Ohio 687.

deficiency, effect on white blood cells of
rats, Fla. 128.

deficiency in rats, effects, 729.

deficiency, night blindness due to, 886.

deficiency, studies, 569.

deficient diet, effect on cutaneous infec-
tions in rats, 423.

determinations, accuracy, 568.

effect on rate of fat absorption in rats,
422.

from pilchard oil for poultry, 680.

in apples, 134.

in butter, effect of soybean feeding, 368.

in butterfat produced on hegarl fodder
and cottonseed meal, N.Mex. 236.

in canned strained vegetables, Mich. 421.

in corn, effect of variety and growth
stage, Mass. 879.

in corn silage, A. I. V., molasses, and
ordinary, Nebr. 687.

in eggs, effect of diet, Iowa 228.

in evaporated milk, effect of irradiation,
423.

in fanfish-liver oil, 729.

in fats, effect of rancidity, Wis. 562.

in local treatment of wounds, 279.

in margarine, 277.

in milk, rate of change, 230.

in milk, rate of change when rations
are varied, Ind. 383.

in ration of hens, effect on eggs and
chicks, 233.

in squash varieties, 278.

in whiting-liver oil, Mass. 879.

minimum requirement of livestock, 830.

requirements for laying hens, 681; Idaho
826; N.J. 527.

requirements of chicks, 232.

requirements of cow for production of
butterfat, Ind. 383.

requirements of laying birds, Ohio 674.

requirements of White Leghorn pullets,
233.

stability in mixed ration, Ohio 674.

standardization and estimation, 297.

transmission from parents to young in
mammals, 423.

utilization by dairy cows, Tex. 237.

Vitamin, antihemorrhagic, see **Vitamin K**.

Vitamin, antineuritic, see **Vitamin B₁**.

Vitamin B₁—

and G in soybeans and corn, comparison,
Ill. 374.

assay, 424.

Vitamin B₁—Continued.

- chemical structure, relation to spectroscopic absorption, 150.
- deficiency, diagnosing with determinations of bisulfite-binding substances in blood, 424.
- deficiency in chicks, genetic resistance, 466.
- deficiency, peripheral nerves in, as observed by polarized light, 137.
- deficient diets, effect on rats, Okla. 136.
- deficient rats, electrocardiographic changes in, 136.
- detection and estimation, reagent for, 151.
- determination by thiochrome reaction, 298.
- effect on rate of fat absorption in rats, 422.
- extraction and stability, 570.
- growth factor for plants, 760.
- in canned strained vegetables, Mich. 421.
- in grain compared with international standard for vitamin B₁, 837.
- in lamb muscle and organs, S.Dak. 136.
- in lamb tissues and organs, S.Dak. 570.
- in seed oils, 135.
- in yeast, 729.
- international standard, and crystalline torulin, 279.
- potency of yeast samples, 743.
- preparations, crystalline, assay methods for comparison, 886.
- test, accuracy, effect of length of test period, 570.
- use of colloidal adsorbents with, 570.

Vitamin B₂, *see* Vitamin G.

Vitamin B₆—

- deficiency and encephalomalacia in chicks, differentiation, 838.
- studies, improved ration for, Wis. 562.

Vitamin B₁₂—

- cane v. beet molasses as source, 830.
- in cereals, 136.
- in milk, human and cow's, 424.

Vitamin B complex—

- biological methods for, 743.
- deficiency in various breeds of fowls, 681.
- deficiency, lesions of rat nervous system in, 887.
- deficient dogs, bacterial resistance in, 545.
- in apples, 134.
- methods of separating constituents, Ohio 674.
- most completely defined factors of, 135.
- new essential dietary factor of, Wis. 521.
- therapy in chronic arthritis, 424.

Vitamin C—*see also* Ascorbic acid.

- and bacterial toxins, relation to tooth structure, 572.
- chemical structure, relation to spectroscopic absorption, 150.
- crystalline, effect on tolerance to tuberculin, 281.

Vitamin C—Continued.

- crystalline, properties, 281.
 - deficiency and subnutrition, excretory test for, 888.
 - deficiency in rheumatic fever, 428.
 - determination by titration, 298.
 - estimation, growth method, 425.
 - excretion in pneumonias, 139.
 - in apples, 134.
 - in cabbage, 280.
 - in canned strained vegetables, determination and variation, Mich. 425.
 - in citrus juices, 731.
 - in corn, effect of variety and growth stage, Mass. 879.
 - in dairy orange beverages, 425.
 - in eyelets and aqueous humor, determination, 10.
 - in human tonsils, 426.
 - in mangoes, 731.
 - in milk and urine of lactating mothers, effect of vitamin C administration, 280.
 - in milk, determination, 690; Ohio 687.
 - in milk, variations in, 239.
 - in pasteurized milk, 95.
 - in Porto Rico sweetpotatoes, 730.
 - in vegetables, 151, 280.
 - in vegetables preserved by cooking, canning, and freezing, stability, Mass. 879.
 - metaphosphoric acid in extraction and titration, 743.
 - origin, Sah's hypothesis, 298.
 - oxidation of, 741.
 - relation to hemorrhagic diatheses, 731.
 - reversibly oxidized forms, duality of, 584.
 - role in animals resistant to scurvy, 138.
 - storage by normal adults following period of low intake, 572.
 - therapy in experimental poliomyelitis, 137, 138.
- Vitamin, cataract-preventive, in cheese, flavine in, 429.
- Vitamin D—
- assay with chickens, 438.
 - deficient diet, effect on dental caries in deciduous teeth, 890.
 - effect on intestinal atony of rickets, 733.
 - effect on intestinal iron reduction, 733.
 - effect on rate of fat absorption in rats, 422.
 - for chicks, Kentucky bluegrass as source, 680.
 - for confined laying hens, sources compared, 523.
 - from cod-liver oil and irradiated cholesterol, efficiency for laying hens, Ohio 674.
 - from pilchard oil for poultry, 680.
 - in blood serum, estimation, 889.
 - in cod-liver oil and irradiated ergosterol, identity, 889.
 - in corn, effect of variety and growth stage, Mass. 879.
 - in eggs, effect of diet, Iowa 228.
 - in fanfish-liver oil, 729.

Vitamin D—Continued.

in feed, ability to transform and convert to milk, breed comparison, S. Dak. 91.

in fish oils, multiple nature, 676.

in margarine, 277.

in milk, seasonal variation, 239.

in whiting-liver oil, Mass. 879.

line test assay for, technic, 889.

milk from feeding irradiated yeast or by direct ultraviolet irradiation, 692.

milk, new developments, Ohio 95.

milk, present status, 890.

milk, reliability of dealers' guarantees of vitamin D content, Mass. 879.

mode of action, 139.

multiple nature of, 888.

potency of milk, effect of roughage, S. Dak. 91.

potency of milk, technic for assaying, Ohio 687.

relation to calcium and phosphorus retention of cows, S.Dak. 91.

requirements of chicks, relation to calcium in ration, 528.

requirements of laying pullets, Wis. 521.

units, energy equivalents, 153.

value of salmon fish meal, effects of storage, 233.

Vitamin D₂, chemical structure, relation to spectroscopic absorption, 150.

Vitamin D₃, chemical structure, relation to spectroscopic absorptions, 150.

Vitamin E—

in royal jelly, tests for, 825.

pea germ meal as source, Idaho 839.

relation to sterility in goats, Iowa 235.

requirement of chicks, Ill. 374.

Vitamin F, *see* Vitamin B₁.

Vitamin G—

and B in soybeans and corn, comparison, Ill. 374.

and pellagra-preventing factor in chicks, differentiation, 233, 234.

chemical structure, relation to spectroscopic absorption, 150.

crystalline, response of rats, chicks, and poult to, 81.

deficiency, stomatitis due to, 572

deficient diets, effect on rats, Okla. 136.

in alfalfa meal, 81.

in certain vegetables, Tenn. 418.

in chick nutrition, 684.

in lamb muscle and organs, S.Dak. 136.

in lamb tissues and organs, S.Dak. 570.

potency of dried milk products, Wash. 375.

requirement of poultry, Wash. 375.

requirements of chickens, Ohio 674.

studies with chicks, Ohio 674.

use of colloidal adsorbents with, 570.

Vitamin K—

mode of action, 377.

studies, 675, 676.

Vitamin P—

proposed name for substance affecting capillary resistance, 739.

Vitamin P—Continued.

steps leading up to, from vitamin C, 740.

Vitamins—

chemical nature, 5.

deficiency, *see* Avitaminosis and *specific vitamins*.

importance in poultry feeding, 679.

in diet of infants and children, 421.

in fruits and vegetables, effect of processing, Mass. 568.

requirements of chicks, 684.

research, recent trends in, 568.

studies, Idaho 894.

Volcanic ash soils, oxyphilic, clay substances, state of, 304.

Voles, activity and home range, 653.

Vulnovitan application to wounds, 279.

Wagons, farm, improvement, Colo. 865.

Walls—

rammed earth, for farm buildings, S.Dak. 109.

retaining, pressure distributions on, 404.

Walnut—

black, seedbeds, necrosis of foliage in, Iowa 200.

hybrids, differences in heterosis, 780.

oil, vitamin B₁ in, 135.

Walnuts, storage and keeping quality, 419.

Warble flies, control in Canada, 663.

Washington College, notes, 897.

Washington Station, notes, 897.

Washington Station, report, 431.

Wasps, Nearctic mutillid, descriptions and records, 670.

Water—

absorption by plants in water culture, wind-tunnel tests, 461.

absorption in plants, relation to rate of transpiration, 598.

and soil conservation in Pacific Northwest. U.S.D.A. 864.

behavior, basic principles, U.S.D.A. 707.

conservation, zoning as technic, U.S.D.A. 707.

consumption and blood sugar level, 885.

cress aphid, new, description, 221.

duty of, *see* Irrigation water.

ground, for drought relief, U.S.D.A. 707.

ground, recharge, artificial methods, U.S.D.A. 707.

heaters, efficiency, Mass. 839.

heaters, electric dairy, Ind. 403.

heating for livestock, Nebr. 706.

lake, poisoning of cattle due to, 103

law in Arizona and neighboring States, Ariz. 110.

level, effect on crop yields on peat lands, Minn. 862.

penetration, effect of deep cultivation, Utah 110.

raw, testing, Mass. 743.

resources and geology of Duval County, Texas, 550.

resources of Nebraska, conservation, 257.

Water—Continued.

- spreading over absorptive areas for storage underground, U.S.D.A. 707.
- supply and flood control, farm ponds for, U.S.D.A. 707.
- supply for orchards, 259.
- supply of United States, 255. 550, 860.
- surface, pathogenic organisms in, N.J. 550.
- table effects on stone-fruit tree diseases, 61.
- use and control in Kansas, 256.

Waterfowl—

- breeding grounds, effect of crows on, U.S.D.A. 809.
- plant distribution and ecology in breeding grounds of northern Iowa, Iowa 173.
- situation, U.S.D.A. 652.
- wild, gizzard worm in, 549.

Watermelon—

- fruit shape and flesh color, inheritance, Iowa 200.
- fungus diseases, Fla. 54.
- prices, factors affecting, U.S.D.A. 123.
- wilt disease, Fla. 54.
- wilt-resistant strains, breeding and selection, Iowa 199.

Watermelons—

- Colletotrichum lagenarium* on, biology and control, Iowa 199.
- culture experiments, Ga. 43; La. 186.
- fertilizer experiments, Ga. 43; La. 186.
- fruit and seed characters, inheritance, Calif. 317.
- variation in soluble solids within individual fruits, 335.
- variety tests, Ga. 43; La. 186.
- wilt-resistant, seedling structure, Iowa 200.

Waters—

- big and little, U.S.D.A. 707.
- little, control and use in France. U.S. D.A. 707.
- subsurface, nature, Fla. 13.

Watershed and hydrologic studies, 162.

Watershed and hydrologic studies, measuring equipment used in, 404.

Watersheds, small, flood discharges from, determination, 110.

Wax emulsions for spraying nursery stock, Mich. 186.

Wax moth larvae diet, wax as necessary constituent, 516.

Weasel, food habits, 211.

Weather—see also Meteorological observations and Meteorology.

- data, [Conn.] Storrs 445.
- forecasting, long-period, U.S.D.A. 12.
- forecasting, seasonal, methods in California, 12.
- phenomena, treatise, 586.
- world, studies, 586.

Weathering, effects in genetic soil classification, 158.

Webworm—

- beet, breaking dormancy, 359.
- fall, scarcity, Conn.[New Haven] 813.

Webworms—

- attacking alfalfa, control, Ill. 359.
- sod, ecology and control, Iowa 215.
- sod, in lawns, control by dichloroethyl ether, 65.

Weed seeds—

- chemicals as agents for killing in seed-beds for lawns, Ohio 615.
- germination, studies, Iowa 180.
- longevity, Utah 40.

Weeds—

- biological control in New Zealand, 815.
- control, Idaho 771; Wash. 325.
- control and nature of herbicidal toxicity, Nebr. 614.
- control in growing corn, Iowa 181.
- control with calcium cyanamide, Tenn. 325.
- eradication program, 259.
- growth in nursery beds, control, Ind. 341.
- losses due to, Utah 40.
- problem under dry farming, Mont. 326.
- winter-hardiness, 781.

Weight control, banana and milk in diet for, Mass. 879.

Wethers, yearling, v. lambs, relative gains, Idaho 826.

Wharf borer, biology, economic importance, and prevention, 668.

Wheat—

- acresages, 1900-1935, Iowa 260.
- Albit, and sweetclover mixtures, as hay and silage crop, value, Wash. 375.
- Albit forage and sweetclover ensiled and cured as hay, 673.
- and rice in diet of rat, comparison, 274.
- and rye, raw and cooked, in poultry rations, comparison, Nebr. 674.
- and wheat products, moisture in, determination, 441.
- as feed for laying hens, 681.
- ash content, effect of fertilizers, Ohio 615.
- availability of iron in, 728.
- behavior on summer fallow v. pea land, Wash. 325.
- black stem rust, varietal resistance, Wyo. 55.
- breeding, Del. 180; Ill. 324; Ind. 825; Iowa 180; Nebr. 614; Tenn. 325; Utah 40.
- bunt, see Wheat smut, stinking.
- climate and yield in region of Paris, 156.
- corn v. sorgo as preparation for, U.S. D.A. 182.
- crosses between drought susceptible and resistant varieties, inheritance in, 175.
- culture experiments, Ga.Coastal Plain 38.
- damage from scab, U.S.D.A. 636.
- diseases, Ind. 343.
- diseases in Massachusetts, U.S.D.A. 636.
- effect of cyanamide applied December 1 on subsequent crops, Md. 625.
- embryo, lipids, Minn. 581.
- experiments on dry land, Utah 40.

Wheat—Continued.

fertilizer experiments, Alaska 770; Del 150; Wash. 325.
 flour, *see* Flour.
 for winter pasture, Tex. 617.
 futures, U.S.D.A. 121.
 germination, action of quinoline derivatives. 170.
 gluten v. blood meal as protein supplement for dairy cows, 236.
 gray shorts, constituents preventing slipped tendons in chicks, 529.
 grinding, value, Okla. 78.
 ground, as substitute for bran and middlings, S.Dak. 70.
 growth under constant conditions, 455.
 head blight and root rot, Tenn. 343.
Helophorus nubilus as serious pest, 76.
 inheritance and improvement studies, Wash. 325.
 insect pest, survey, Iowa 215.
 irrigation experiments, 961.
 leaf rust, effect on yield, composition, and quality, Ind. 343.
 leaf rust in Texas, U.S.D.A. 343.
 leaf rust, physiologic races, revision of numbers assigned to, U.S.D.A. 346.
 light and heavy, digestible nutrients and metabolizable energy, 673.
 loose smut, physiologic forms, 496.
 loose smut, serious in Kansas, Oklahoma, and Texas, U.S.D.A. 492.
 market in Spain, new regulation, 265.
 meal fermentation time test, 439, 624.
 mosaic in different counties, Ill. 324.
 new red-chaffed, red-kerneled, for Ohio, Ohio 615.
 oats, and corn, relative efficiency against pizzard lesions in chicks, Wis. 322.
 of Ohio, productivity, relation to awns, 750.
 offals, digestibility tests with poultry, 350.
 perennial, tests, S.Dak. 39.
 pest, sporadic, in Montana, 823.
 policy of France, 265.
 policy, recent French, appraisal, U.S. D.A. 712.
 powdery mildew, reaction of certain varieties to, U.S.D.A. 493.
 preeminence in human dietary, 418.
 root rot infection, effect of mechanical seed injury, 202.
 root rot, seed treatment for, 202.
 rust, *see* Rusts and Wheat leaf rust and Wheat stem rust.
 scab, control, Wyo. 55.
 seasonal storage in China, 415.
 seed improvement, Ind. 325.
 seed-borne plant pathogens, treatment for, Iowa 200.
 seedling, Ohio 780.
 seedlings, expressed juice in, refractive indexes, 762.
 sick, notes, Ohio 637.
 sick, role of fungi in, Ohio 497.
 situation, Okla. 551.

Wheat—Continued.

smut—*see also* Smut(s).
 resistance, breeding for varieties adapted to Arizona conditions, Ariz. 203.
 smut, stinking—
 control, Wyo. 55.
 copper-lime-arsenate dusts for, 198.
 degree of resistance for commercial production, 346.
 resistance in wheat cross, genetics of, 176.
 resistance to physiologic forms, Wash. 325.
 seed treatments for control, Idaho 794.
 unusual amount in Texas, U.S.D.A. 492.
 varietal resistance, Wyo. 55.
 spring, breeding, Idaho 770; S.Dak. 30.
 spring, culture experiments, Wyo. 40.
 spring, date of seeding experiments, Mont. 326.
 spring, effect of manure on nonirrigated crops, Wyo. 40.
 spring, tillage experiments, U.S.D.A. 743.
 spring, variety tests, Idaho 770; Ill. 324; Nebr. 614; U.S.D.A. 182; Utah 40; Wash. 325; Wyo. 40.
 spring, yields, U.S.D.A. 773; Wis. 474.
 spring, yields, effect of tillage, Mont. 325.
 spring-sown, variety tests, N.Mex. 181.
 stem rust—*see also* Rusts and Wheat leaf rust.
 in Minnesota and North and South Dakota, U.S.D.A. 794.
 losses in western Canada, 796.
 reports, U.S.D.A. 636.
 studies, U.S.D.A. 636.
 stripe rust, effect on growth, water economy, and yield, 346.
 use in turkey rations, S.Dak. 79.
 varieties and classes, distribution in United States, U.S.D.A. 478.
 varieties, breaking strength of straw, changes in from heading to maturity, 623.
 varieties for livestock feed, Utah 40.
 varieties of West, chemical, milling, and baking results, U.S.D.A. 479.
 variety-cultural experiments, Iowa 180.
 variety tests, Ga.Coastal Plain 33; Iowa 180; N.J. 473; Okla. 39; Pa. 39; S.C. 39; Tenn. 325; U.S.D.A. 182; Wyo. 40.
 winter, breeding, Idaho 770; S.Dak. 39.
 winter, cold resistance in transition from dormancy to active growth, 781.
 winter, controlled freezing studies with, Nebr. 614.
 winter, culture experiments, Wyo. 40.
 winter, date of seeding experiments, Mont. 326.
 winter, fermentation time tests, Ill. 324.
 winter-sown, variety tests, N.Mex. 181.

Wheat—Continued.

- winter, tillage experiments, U.S.D.A. 774.
- winter varieties, analyses of yields, Ill. 324.
- winter varieties, cold resistance, comparison, 780.
- winter, variety tests, Idaho 770; Ill. 324; Nebr. 614; Utah 40; Wash. 325; Wyo. 40.
- winter, yields, Wis. 474.
- winter, yields, effect of tillage, Mont. 325.
- yields per acre, Ohio 711.

Wheatgrass, crested—

- breeding experiments, Idaho 770.
- culture experiments, Wyo. 40.
- production tests, U.S.D.A. 182.
- stinking smut on, 639.
- v. native grass pasture for sheep, Wyo. 80.

Wheels, steel, tests on farm tractors, Mont. 710.

Whipworm from ocelot, 656.

Whipworms in dogs, 252.

White ants, *see* Termites.

White grubs—

- attacking lawns in Ohio, Ohio 658.
- control in tobacco beds, effect of burning, Ky. 814.
- devastations in Iowa nurseries, 822.
- pest of pastures in Queensland, 822.
- studies, Ind. 360; Iowa 215.
- survey, Ky. 814.

White pine—

- blister rust—
 - aeciospores, possibility of *Ribes* infection above 19° C., 354.
 - age of needles, relation to infection, 68.
 - control, Conn.[New Haven] 637; Ohio 637.
 - control and barberry eradication, U.S.D.A. 342.
 - immunity of Viking red current from, 650.
 - in Iowa, control, Iowa 200.
 - manual for field men, 649.
 - progress in planted area, 650.
 - progressive intensification, 64.
 - surveys, U.S.D.A. 794.
 - teliospores, method for separating, 650.
- root and butt rot in, cause, 650.
- weevil, studies, 659.

Whiteflies, control with lime-sulfur, Fla. 65.

Whitefly—

- fall clean-up measures against, 219.
- rhododendron, control, U.S.D.A. 514.

Whitetop, control, Wyo. 40.

Whiting-liver oil, vitamin A and D content, Mass. 879.

Wildfire, control in tobacco plant beds, 196.

Wildlife—

- a land crop favorable to water and soil conservation, U.S.D.A. 707.
- in land planning, U.S.D.A. 652.

Wildlife—Continued.

- research units, cooperative, accomplishments, U.S.D.A. 652.
- resources, conservation, and upstream engineering, U.S.D.A. 707.
- review, U.S.D.A. 653.
- Williams, C. G., retirement, editorial, 1.
- Willow leaves, calcium and phosphorus content, Wyo. 80.
- Willow scab in Vermont, U.S.D.A. 636.
- Wind erosion—
 - area of southern Great Plains, soil conservation survey, U.S.D.A. 18.
 - control, emergency, U.S.D.A. 20.
 - control in southern High Plains region, 162.
 - control, recommendations for research relating to, 162.

Winbreaks, *see* Trees, shelterbelt.

Wine, Muscatel, spoilage due to wild yeasts, 443.

Wines—

- French, guaranteed quality, U.S.D.A. 551.
- sweetened, preparation and preservation, 443.

Wireworm—

- eastern field, abundance on tobacco, Conn.[New Haven] 362.
- injury to tobacco, control, Ky. 814.

Wireworms—

- control by carbon bisulfide carrying naphthalene or PDB, 363.
- in soil, effect of temperature and moisture, Idaho 814.
- notes, 106.
- sampling soil for, 372.

Wiring systems for farm buildings, 259.

Wisconsin Station, report, 575.

Wisconsin University, notes, 288.

Witches-broom of *Tabebuia pallida* caused by a virus, 196.

Wohlfahrtia—

- meligenit*, notes, 812.
- rigii*, larval stages, 663.
- rigii*, notes, 848.

Women—

- rural, and Works Progress program, analysis of levels of living, Mo. 538.
- young, basal metabolism in Hawaii, 420.

Wood—*see also* Timber.

- as butter containers, tests for odor and flavor, U.S.D.A. 97.
- basket veneer and handle stock, marketing, Ind. 341.
- cell walls in, chemistry of, 166.
- compression, structure, occurrence, and properties, U.S.D.A. 52.
- lots, management, Ind. 341.
- pulping with alcohols and other organic reagents, 154.
- rate of decay, effect of nitrogenous compounds, 652.
- sugar, use in pig fattening, 85 936.
- sugar yeast as source of protein to working horses, 86.

Wood—Continued.

sugar yeast, feeding value, 230, 820
 tracheid walls, cellular structure, 763.
 treatment for termite control, Ill. 360.

Woodchuck, animal parasites of, 360.

Woodcocks, chromosomes in, morphology, 464.

Woodlands grazed, restocking, Ohio 634.

Woody—

dicotyledons, vessel length determination in, 763.

plants—

direct seeding in erosion control, 193.

for erosion control, U.S.D.A. 21.
 key, 756.

seedlings and cuttings, damping-off
 and growth, Mass. 795.

starch in, determination, 744.

stems and roots, microscopic sections,
 technic for preparing, 764.

Wool—

chemistry, relation to susceptibility of
 sheep to blowfly attack, 370.

formaldehyde as protective agent, Iowa
 263.

growth and properties, effect of quan-
 tity of feed, 834.

growth, gradients in, 677.

kinds, effect on physical properties of
 flannel, S.Dak. 140.

Merino, crimp of, 677.

on grade, results of marketing, Okla.
 260.

production and shrinkage, effect of local-
 ity and management, Utah 80.

quality, assessment, 677.

raw, determination of yield from density
 under pressure, 526.

raw, predicting yield, 678.

shrinkage, Wyo 140.

virgin, bats and wool-filled comforters
 in California, regulations for, 254.

Woolly aphid, *see* Apple aphid, woolly.

Wounds, local treatment with vitamin A oil
 279.

Wrens, house, yearly abundance, 654.

Wyoming—

State experiment farms, report, 142.

Station, notes, 897.

Station, report, 142.

University, notes, 897.

Xenophthalmia and lesions in sensory nerve
 of eye, relation to vitamin A deficiency,
 568.

X-ray irradiation, attenuation of fowl pest
 virus by, 253.

X-rays, effect on pigment formation, 819.

Xylan, fermentation products, Iowa 147.

Xylem *aurumica* damage to teak timber,
 216.

Xylorycta luteotactella, damage to nut trees,
 519.

Yam wilt associated with *Fusarium*, P.R.Col
 795.

Yams, fertilizer experiments, P.R.Col. 771.

Yams, varieties for Hawaii, Hawaii.Sugar
 Planters' 479.

Yautias, variety tests, P.R.Col. 771.

Yeast—

irradiated, antirachitic value for in-
 fants, 732.

manufacture, research, Wis. 437.

S and R forms, fermentation products,
 293.

types in gassy sweetened condensed milk,
 243.

vitamin B in, factors affecting, Wis. 562.

vitamin B₁ in, 729.

Youngberries—

cold storage, Fla. 128

preservation, Fla. 43.

Youth—

community surveys, 417.

in Texas relief population, 560.

rural, of Wisconsin, education and occu-
 pation, Wis. 126.

rural, unmarried, activities, interests,
 and problems, [N.Y.]Cornell 126.

Zatropis incertus, parasite of apple curculio,
 N.Y.State 75.

Zebra caterpillar, pyrethrum as insecticide
 for, 367.

Zein, preparation, 147.

Zinc—

and copper, comparative nutritive ef-
 fects, Mass. 748.

arsenate, stickers used with, 309.

as essential element for sugar beets and
 potatoes, 29.

determination methods, Fla. 7.

effect on tomatoes, 450.

function in animal body, Wis. 562.

in foods, determination, 206.

in soils, behavior, Fla. 13.

poisoning of pigs, chronic, 836.

role in crop production, 166.

sulfate as corrective for arsenical in-
 jury to peaches, Ill. 336.

sulfate treatments for little leaf of fruit
 trees, 803.

Zonosemata electa, notes, Conn.[New Haven]
 813.

Zoology, relation to veterinary science, 848.

Zoopage n.sp., description, 345.

Zygadenus gramineus, poisonous constituents
 in, Wyo. 101.
